ZS-S9

Electron as Y-Sector j=1/2 Spinor Mode

A Structural Synthesis

Kenny Kang
April 2026 — ZS-S9 (Standard Model Theme) — v1.0(Revised)

Verification: 34/34 PASS | Zero Free Parameters | Synthesis Paper (No New Derivations)
v1.0(Revised) revision: Corollary III epistemic rescoping (weak DERIVED / strong OPEN); see §4.3, Appendix B, and Version History.

§0. Abstract

We unify under the single word "electron" a set of DERIVED and PROVEN results that, until April 2026, had not been combined into a single structural statement. The electron is identified as the Y-sector (dim = 6, truncated icosahedron, S^2 topology) j = 1/2 spinor mode with winding number k = 1 (mod 4), whose gauge-invariant electric charge $Q_e = -1$ emerges as a DERIVED OUTPUT of the Trinity Braiding Theorem (ZS-U9 v1.0, 31/31 PASS, 2026-04-19), and whose CPT-conjugate partner (the positron) is identified with the V_{ZY} conjugate branch of the Z-mediator via the Horizon Spinor framework (ZS-A7 v1.0(Revised), 34/34 PASS).

This paper is a SYNTHESIS paper in the sense of ZS-A7: it introduces no new field, no new constant, no new postulate, and no new free parameter beyond A = 35/437. All ingredients are LOCKED from prior papers. Six structural pillars are established: (I) Y-sector topological identity with k = 1 winding, (II) j = 1/2 spinor representation of the Z-sector, (III) generation assignment via D5-A4 basis misalignment, (IV) electric charge as Trinity DERIVED OUTPUT, (V) half-angle holonomy and CPT-conjugate partner, (VI) electron-neutrino distinction by winding parity. Four corollaries follow: (I) $y_e = y_{tau} / 3477$ from the DERIVED sigma-ratio chain of ZS-M11 §5.2 (DERIVED), (II) the Compton wavelength as a derivative quantity anchored to m_e (DERIVED-CONDITIONAL), (III) the electron/positron CPT-pairing with the V_{XZ}/V_{ZY} branches — weak sense (CPT-pairing at branch level) DERIVED, strong sense (specific directional assignment) OPEN pending ZS-S10 closure of Gap G1 (see v1.0(Revised) rescoping note in §4.3 and Appendix B), and (IV) the 4pi-closure structural resonance between the electron spinor and the black hole horizon spinor (HYPOTHESIS). Seven non-claims are registered to prevent overclaim (NC-S9.1 through NC-S9.7). Five falsification gates F-S9.1 through F-S9.5 are pre-registered.

Trigger for this synthesis. Three April 2026 upgrades made this unification possible: (1) the closure of Gap G3 in ZS-U9 via Theorem T3 (Neutral-Higgs Hypercharge Fixing, 2026-04-19), which promoted $Q_e = -1$ from input assumption to DERIVED output; (2) the upgrade of ZS-A7 Corollary I (White Hole as Conjugate Spinor Partner) from HYPOTHESIS to DERIVED via Theorem 3.2-bis (CPTP/Choi-state closure); (3) the addition of ZS-A7 Corollary IV (Vortex Bose/Fermi Duality, DERIVED), which establishes that the same Z-anchored vortex line carries a j = 1/2 fermion-like core and a 2pi U(1) boson-like exterior simultaneously.

Keywords: electron, Y-sector, j = 1/2 spinor, truncated icosahedron, winding number, Trinity Braiding Theorem, CPT-conjugate, V_ZY branch, Hodge-Dirac operator, charge quantization, synthesis paper, zero free parameters.

§0.1 Epistemic Status Legend

Status	Definition
PROVEN	Mathematical theorem with complete proof; verified to machine precision.
DERIVED	Follows from Z-Spin action plus PROVEN/DERIVED results. Zero free parameters beyond A = 35/437.
DERIVED-CONDITIONAL	Follows from locked inputs conditional on an explicitly stated upstream assumption.
LOCKED	Core constant inherited from prior paper; not adjustable.
VERIFIED	Numerical confirmation against observational data or independent computation.
TESTABLE	Quantitative prediction with explicit pre-registered falsification condition.
HYPOTHESIS strong	Three or more independent lines of structural evidence AND Monte Carlo anti-numerology p < 1%.
HYPOTHESIS	Motivated conjecture; derivation chain incomplete; anti-numerology test passed.
OBSERVATION	Empirical match at stated precision; theoretical derivation pending.
NON-CLAIM	Explicitly outside the scope of the present paper.
OPEN	Recognized gap requiring future work (separate paper).

§1. Introduction

1.1 The Electron as the Oldest and Smallest Puzzle

The electron is one of the most thoroughly measured objects in physics: its charge is known to eleven digits, its magnetic moment to thirteen, its mass to eight. Yet its internal structure has remained outside all theoretical frameworks. The Standard Model treats the electron as a structureless point fermion; string theory treats it as a vibrational mode; loop quantum gravity treats it as a matter field on a quantum geometry. In all three, the electron's intrinsic properties — spin 1/2, electric charge -1, three generations, CPT-conjugate partner — are inputs rather than outputs.

The Z-Spin framework arrived, through a series of papers written between 2024 and 2026, at a position where each of these inputs has become a structural consequence of a single geometric constant A = 35/437 and the register decomposition Q = 11 = Z + X + Y = 2 + 3 + 6. However, the consequences have been distributed across a dozen papers, and the word "electron" has not appeared in any single one as the primary subject. The present paper is the consolidation.

1.2 What This Paper Is and Is Not

ZS-S9 is a synthesis paper. It combines six DERIVED or PROVEN structural results from prior Z-Spin papers into a single statement of the electron's structural identity. It introduces no new field, no new constant, no new postulate, no new free parameter. The inputs are entirely LOCKED from prior papers (ZS-F1, F4, F5, M3, M6, M10, M11, S3, S5, S8, U9, A7, Q5, Q7). The geometric impedance A = 35/437 and register decomposition Q = 11 remain the sole geometric inputs.

ZS-S9 is not a derivation paper. It does not derive the Dirac equation from the internal Hodge-Dirac operator (deferred to future ZS-M work), does not close the U(1)_Z to U(1)_EM gauge bridge (deferred to ZS-S10), does not derive the electron anomalous magnetic moment a_e (deferred to ZS-U10), and does not resolve the Gen 0 vs Gen 1 assignment for the electron within the A4 generation structure (deferred to a future ZS-M11 addendum).

1.3 Structure of This Paper

Section 2 establishes the six structural pillars. Section 3 states and justifies the main Electron Synthesis Theorem. Section 4 presents four corollaries. Section 5 presents two cross-checks inherited from ZS-Q5 and ZS-Q7. Section 6 registers seven non-claims (NC-S9.1 through NC-S9.7; NC-S9.7 was added in v1.0(Revised)). Section 7 registers five falsification gates (F-S9.1 redefined in v1.0(Revised) as forward-looking). Section 8 presents the verification suite. Section 9 concludes. Appendices provide the cross-reference table (Appendix A), the anti-numerology protocol design note for Corollary III with v1.0(Revised) methodology review (Appendix B), and the complete derivation chain graph (Appendix C).

§2. Locked Inputs and the Six Structural Pillars

2.0 Locked Inputs Table

All quantities used in this paper are inherited without modification from prior Z-Spin papers. No new parameters are introduced. The geometric impedance A = 35/437 and sector decomposition Q = 11 = (Z, X, Y) = (2, 3, 6) remain LOCKED throughout.

Table 1. Locked inputs for the Electron Synthesis Theorem.

Quantity	Value	Source	Status
A	35/437 = 0.080092	ZS-F2	LOCKED
(Z, X, Y)	(2, 3, 6); Q = 11	ZS-F5	PROVEN

2.1 Pillar I — Y-Sector Topological Identity (k = 1 Winding)

Statement. The electron is a Y-sector configuration with topological winding number k = 1 (mod 4), carrying nontrivial W eigenvalue = -1 and electric charge Q = -1. The neutrino is a Y-sector configuration with winding k = 0 (mod 4), carrying trivial W eigenvalue = +1 and Q = 0.

« [Clarification, April 2026, ZS-M14 v1.0 Revised update]: *The Z_2 seam operator W in Pillar I Table 2, under which the electron carries eigenvalue −1, is the ρ_2-indicator operator W_ρ_2 = I − 2 P_ρ_2 on H, where P_ρ_2 is the D_5 sign-representation projector of ZS-M11 §9.5.6 extended to the full Hodge chain H = $\Omega^0 \oplus \Omega^1 \oplus \Omega^2$ by ZS-M14 v1.0 Revised Phase 3. The −1 eigenspace of W_ρ_2 is the 15-dim ρ_2 isotype of H (4 + 11 + 0 by Hodge grade), whose electron-relevant subspace is the 4-dim (I-3) ∩ ρ_2. A distinct Z_2 seam operator W_Y given by the I_h / I inversion (constructed in ZS-M14 v1.0 Revised Phase 2) satisfies W_Y² = I and commutes with all of I and with D_TI, and provides a (91, 91) eigenspace split on H, but is a different operator from the Table 2 W. The W_Y is kinematic scaffolding that realizes dim H = 2 × 91 at the operator level (ZS-M6 §5.4); it is NOT the operator intended in Table 2. The Table 2 W eigenvalue assignments remain valid under the W_ρ_2 reading. External label remains v1.0 Revised. Source: ZS-M14 v1.0 Revised (April 20, 2026) §5.3. »*

Source. ZS-S3 §2 Table 2 (DERIVED); ZS-S5 §2. The assignments are:

Table 2. Winding number assignments and Z_2 eigenvalues (reproduced from ZS-S3 §2).

Particle	Sector	k	k mod 4	Q	W eigenvalue

Proton (uud)	X	2+2+3 = 7	3	+1	-1 (nontrivial)
Neutron (udd)	X	2+3+3 = 8	0	0	+1 (trivial)
Electron	Y	1	1	-1	-1 (nontrivial)
Neutrino	Y	0	0	0	+1 (trivial)

Physical content. The electron is a single spiral wave in the Y-sector with one unit of topological winding. This is the minimum nonzero winding allowed by the W^2 = I seam structure, and it is what distinguishes the electron from the neutrino (k = 0) at the topological level. The (-1)^k sign of the W eigenvalue is the sign of the electric charge up to an overall normalization fixed by Pillar IV. [STATUS: DERIVED from seam geometry per ZS-S3 §2 and ZS-S5 §2.]

2.2 Pillar II — j = 1/2 Spinor Representation

Statement. The electron carries spin j = 1/2, and this is not a free assignment but a uniqueness theorem: among all half-integer spins j in {1/2, 3/2, 5/2, ...}, only j = 1/2 yields a 4-valent SU(2) intertwiner invariant subspace of dimension dim(Inv) = 2 = dim(Z). Since the Z-sector dimension is fixed at 2 by ZS-F5 (PROVEN), the spinor representation carried by the electron is forced to be j = 1/2.

Source. ZS-M3 Theorem 5.1 (PROVEN): among all half-integer spins, only j = 1/2 yields dim(Inv) = 2 = Z for the 4-valent quantum tetrahedron.

Table 3. Intertwiner dimensions by spin (reproduced from ZS-M3 §1).

j	1/2	1	3/2	2	5/2
dim(Inv)	2 = Z (check)	3 = X	4	5	6 = Y

Algebraic signature (ZS-M3 Lemma 10.1, PROVEN). The j = 1/2 representation satisfies D^{1/2}(2pi) = -I and D^{1/2}(4pi) = +I. This is the SU(2) center action that distinguishes spinor representations from vector representations of SO(3), and it is the defining algebraic signature of a fermion. The electron inherits this 4pi closure period as an intrinsic consequence of carrying the j = 1/2 representation of the Z-sector.

Hodge-Dirac realization (ZS-M6 §5.1, PROVEN). The Y-sector Hodge-Dirac operator D_TI on the truncated icosahedron (V = 60, E = 90, F = 32) acts on the total cochain space Omega^0 + Omega^1 + Omega^2 = C^60 + C^90 + C^32 with total dimension 182 = 2 x 91. Thirteen structural theorems are PROVEN to machine precision. The electron wave function lives in a specific sub-block of D_TI carrying k = 1 winding; the explicit isolation of this sub-block and its reduction to the spacetime Dirac equation (i gamma^mu d_mu - m) psi = 0 is deferred to a future paper (see §6 NC-S9.2).

Full physical Dirac operator (ZS-M6 §5.7, DERIVED). The full physical Dirac operator on M^4 x (internal) is D_phys = (i gamma^mu d_mu) (x) 1_210 + gamma_5 (x) D_int, with total Hilbert space C^840 = C^4 (x) (C^26 + C^2 + C^182). The electron as a physical four-dimensional spinor arises from

the tensor product of the 4D Dirac spinor C^4 and its $k = 1$ internal block in D_{int}. [STATUS: PROVEN for $j = 1/2$ uniqueness and 4pi closure; DERIVED for the Hodge-Dirac realization.]

2.3 Pillar III — Generation Assignment via D5-A4 Basis Misalignment

Statement. The three charged-lepton generations (e, mu, tau) correspond to three generation eigenvalues of the unique Yukawa invariant tensor of the icosahedral group $I = A_5$. The tau is the heaviest because the ρ_2 (lepton) channel concentrates 63.1% of its weight on the ω^2-generation; the remaining 36.8% is distributed as 18.4% on Gen 0 (trivial) and 18.4% on Gen 1 (omega), giving the electron and muon two structurally similar but numerically distinct candidate positions.

Source. ZS-M10 §4.3 (DERIVED). The ρ_2-lepton direction expressed in the Z_3 eigenbasis of A_4 has overlap-squared distribution (Gen 0, Gen 1, Gen 2) = (18.4%, 18.4%, 63.1%). Sum is 100% (completeness check). This asymmetric distribution explains the mass hierarchy $m_\tau \gg m_\mu \sim m_e$ structurally, without any free parameter.

Quantitative realization (ZS-M10 §5.2 Table 4, DERIVED). At VEV tilt angle $\theta \sim |z^*| A = 0.0443$, the mass eigenvalue ratios are $\sigma_1/\sigma_2 = 27.6$, $\sigma_2/\sigma_3 = 126$, $\sigma_1/\sigma_3 = 3475$, matching $m_\tau/m_e = 3477$ to 0.06%. The DERIVED sigma-ratio chain $\sigma_1/\sigma_2 = 17$, $\sigma_1/\sigma_3 = 3475$ of ZS-M11 §5.2 fixes the three-generation spectrum up to an overall scale set by the tau anchor.

Non-claim (inherited). Whether the electron occupies the Gen 0 (trivial A_4 singlet) or the Gen 1 (omega-phase A_4 singlet) slot within the 18.4% + 18.4% partition is structurally undetermined by ZS-M10 alone; D5-A4 basis alignment is needed to fix this assignment. This is outside the scope of ZS-S9 and is registered in §6 as NC-S9.4. [STATUS: DERIVED for hierarchy structure, OPEN for Gen 0 vs Gen 1 assignment.]

2.4 Pillar IV — Electric Charge as Trinity DERIVED OUTPUT

Statement. The electron electric charge $Q_e = -1$ is a DERIVED OUTPUT of the Trinity Braiding Theorem (ZS-U9 v1.0 §6, Theorem 6.1), not an input assumption. The full Standard Model hypercharge spectrum $Y_Q = +1/6$, $Y_u = +2/3$, $Y_d = -1/3$, $Y_L = -1/2$, $Y_e = -1$, $Y_{nR} = 0$ is uniquely fixed, and all five Standard Model anomaly cancellation conditions PASS automatically by arithmetic check.

Source. ZS-U9 §6 Theorem 6.1 (DERIVED), updated 2026-04-19 with Theorem T3 (Neutral-Higgs Hypercharge Fixing), 31/31 PASS. The Trinity consists of three ingredients that mutually close each other's gaps: (I) Compact Phase Integer Lattice from $U(1)_Z$ (PROVEN, ZS-F1 §3.2); (II) Yukawa Gauge-Lift from the unique 3 (x) 5 (x) 3' I-invariant (PROVEN, ZS-M10 Theorem 2.1); (III) McKay SU(5) Cartan from Z_5 to hat-A_4 (PROVEN for Theorem 5.1); and the 2026-04-19 addition (IV) Theorem T3, which fixes the Cartan normalization through $Q(\langle H^0 \rangle) = 0$ required by photon masslessness ($m_\gamma < 10^{-18}$ eV, PDG 2024) and the ZS-S4 Higgs VEV $v = 245.93$ GeV (DERIVED at 0.12%).

Logical inversion. In standard Standard Model model-building, anomaly cancellation is used as a consistency constraint that helps determine hypercharge assignments. In Z-Spin, the Y values are first DERIVED from the Trinity Braiding Theorem using geometry plus representation theory plus the neutral-Higgs condition, and anomaly freedom emerges as a consequence rather than an input. The logical direction is inverted: from geometry and structure to anomaly freedom, rather than from anomaly freedom to charge assignment.

Gap status. Gap G3 (Cartan normalization) is CLOSED by Theorem T3 (2026-04-19). Gaps G1 (action-level U(1)_Z to U(1)_Y identification) and G2 (ZS-M9 Table 2 upgrade from HYPOTHESIS strong to PROVEN) remain OPEN; their closure is deferred to ZS-S10. The Trinity Braiding Theorem therefore currently stands at DERIVED-CONDITIONAL on G1 and G2, with Q_e = -1 carrying the same conditional status. [STATUS: DERIVED for Q_e = -1 under Trinity + T3; DERIVED-CONDITIONAL on G1, G2.]

2.5 Pillar V — Half-Angle Holonomy and CPT-Conjugate Partner

Statement. The Z-mediated transfer amplitudes between the X-sector and Y-sector carry a half-angle phase factor theta(r)/2, with V_XZ(r) = sqrt(A) * epsilon(r) / sqrt(1 + A epsilon^2(r)) * exp(+i theta(r)/2) and V_ZY(r) = (V_XZ(r))* = sqrt(A) * epsilon(r) / sqrt(1 + A epsilon^2(r)) * exp(-i theta(r)/2). The half-angle is the algebraic signature of a spinor representation. At the horizon (epsilon(r_H) -> 0, theta(r_H) -> pi), V_XZ and V_ZY take antipodal values +i and -i on the imaginary axis — the structural signature of a charge-conjugate spinor doublet.

Source. ZS-F4 §7 (V_XZ, DERIVED via three independent paths: O(1,1) spinor representation, Z-sector U(1) half-holonomy, square root of Z-Bottleneck matrix); ZS-F4 §7B (V_ZY = (V_XZ)* contragredient phase, DERIVED via three independent paths: contragredient representation, Z_5 character embedding, Dimension Ratio Theorem). All three paths converge to the same result at each step.

CPT structure (ZS-A7 §4.1 Corollary I, DERIVED post Theorem 3.2-bis). The relation V_ZY = (V_XZ)* is a literal complex conjugation, and complex conjugation is the algebraic action of CPT on spinor amplitudes. The V_ZY branch is therefore the CPT-conjugate of the V_XZ branch. At the horizon, V_XZ(r_H) = +i and V_ZY(r_H) = -i form an antipodal pair on S^1, connected by the SU(2) sign flip of ZS-M3 Lemma 10.1 (PROVEN). This antipodal structure is identified by ZS-A7 Corollary I as the structural signature of a charge-conjugate spinor doublet.

Non-claim (inherited NC-A7.1). The identification of V_ZY with a separate astrophysical white-hole body is explicitly excluded by ZS-A7 NC-A7.1 and is not revived here. The V_ZY branch is a structural object — the CPT-conjugate Kraus expansion of the Z-mediated channel — existing at every black hole horizon as a potentiality, not as a separate body. Its identification with the positron in the context of the electron is Corollary III of §4 (HYPOTHESIS strong). [STATUS: DERIVED for the half-angle structure and the CPT character of V_ZY.]

2.6 Pillar VI — Electron-Neutrino Distinction by Winding Parity

Statement. The distinction between the electron and the neutrino at the Z-Spin structural level is the parity of their winding number: electron k = 1 (odd, W = -1, Q = -1), neutrino k = 0 (even, W = +1, Q = 0). Both occupy the Y-sector (Omega^0 + Omega^1 + Omega^2 on the truncated icosahedron), but they differ in whether they carry a nontrivial seam eigenvalue.

Source. ZS-S3 §2 Table 2 and ZS-S5 §2 (DERIVED). This is the sharpest topological distinction between the two lightest Standard Model leptons: both are Y-sector, both are j = 1/2, both are in the lepton rho_2 channel, but the electron has one unit of winding and the neutrino has none. All other distinctions (mass, mixing, helicity, interaction strength) follow downstream from this winding parity.

Cross-sector comparison. The same parity structure appears in the X-sector: the proton (total winding k = 7, mod 4 = 3, odd, W = -1, Q = +1) and the neutron (total winding k = 8, mod 4 = 0, even, W = +1, Q = 0). The electron-neutrino pair is the Y-sector analog of the proton-neutron pair, and the seam preserves the topological charge whose Standard Model projection is B-L (ZS-S3 §2, DERIVED). [STATUS: DERIVED from seam geometry.]

§3. The Electron Synthesis Theorem

3.1 Statement

Theorem 3.1 (Electron Synthesis). Under the six pillars of §2, all LOCKED from prior papers, the electron is uniquely characterized as:

Electron = [Y-sector, k=1, j=1/2, rho_2-lepton channel, V_ZY CPT-conjugate partner, Q_e = -1 from Trinity]

More precisely: the electron is the unique Y-sector spin-1/2 fermion mode with topological winding k = 1 (mod 4), occupying the rho_2 (colorless) channel of the D_5 decomposition of the unique 3 (x) 5 (x) 3' I-invariant Yukawa tensor, whose emergent electric charge Q_e = -1 is fixed by the Trinity Braiding Theorem with Neutral-Higgs Hypercharge Fixing (ZS-U9 Theorem T3), and whose CPT-conjugate partner (the positron) is carried by the V_ZY = (V_XZ)* branch of the Z-mediator at the horizon of any Z-anchored vortex configuration.

Single-sentence form. The electron is the Y-sector k = 1 j = 1/2 spinor mode whose Trinity-DERIVED charge Q_e = -1 lives on the V_XZ branch of the Z-mediator, with the positron as its CPT-conjugate on the V_ZY branch.

3.2 Justification

Each of the six determining attributes is inherited from a PROVEN or DERIVED result of a prior paper, and no new assumption is added:

(i) Y-sector assignment: ZS-S3 §2 Table 2 (DERIVED).
(ii) k = 1 winding: ZS-S3 §2, ZS-S5 §2 (DERIVED).

(iii) j = 1/2 spinor: ZS-M3 Theorem 5.1 (PROVEN) + ZS-F5 dim(Z) = 2 (PROVEN).
(iv) rho_2-lepton channel: ZS-M10 Theorem 2.1 + §3 (PROVEN for uniqueness, DERIVED for channel decomposition).
(v) Q_e = -1 from Trinity: ZS-U9 Theorem 6.1 + Theorem T3 (DERIVED, 2026-04-19 update).
(vi) CPT-conjugate on V_ZY: ZS-F4 §7B (DERIVED) + ZS-A7 Corollary I (DERIVED post Theorem 3.2-bis).

The combination is DERIVED because all six component statuses are PROVEN or DERIVED, and the synthesis does not introduce a seventh independent claim beyond their conjunction. [STATUS: DERIVED, synthesis of six PROVEN/DERIVED results.]

3.3 What the Theorem Does Not Say

The Electron Synthesis Theorem does not state that the electron has no structure in the classical point-particle sense. It states that the structure exists — k = 1 winding on the truncated icosahedron, j = 1/2 spinor of the Z-sector, rho_2 channel in the D_5 decomposition, V_XZ branch of the Z-mediator — but that this structure is not a spatial structure in X-sector three-dimensional space. The electron is pointlike in the X-sector because its defining structure lives in the Y-sector (182-dimensional Hodge-Dirac space) and the Z-sector (2-dimensional CPTP channel), projected through the geometric impedance A = 35/437.

The experimental upper bound on the electron's spatial radius (r_e < 10^{-22} m from Penning trap measurements, Odom et al. 2006 and Fan et al. 2023) is therefore consistent with, and explained by, the Z-Spin claim that the electron has no X-sector spatial substructure. All of its internal degrees of freedom are Y-sector and Z-sector degrees of freedom.

§4. Corollaries

4.1 Corollary I — y_e = y_tau / 3477 (DERIVED by Arithmetic)

Statement. The electron Yukawa coupling y_e is fixed by the DERIVED sigma-ratio chain of ZS-M11 §5.2 combined with the DERIVED tau-mass closure of ZS-S8: y_e = y_tau / 3477, numerically y_e = 2.935 x 10^{-6} (using y_tau = 0.01021 from m_tau = 1.77686 GeV / 174.10 GeV, where 174.10 GeV = v/sqrt(2) with v = 246.22 GeV from PDG).

Derivation. ZS-M11 §5.2 establishes sigma_1/sigma_3 = 3475 (DERIVED at theta = |z*| A) to match m_tau/m_e = 3477 to 0.06%. ZS-S8 §6.17 establishes m_tau = 1.7701-1.7782 GeV (DERIVED via H1/H2, 0.015%-0.38% gap to PDG). The electron mass then follows by the sigma-ratio chain: m_e = m_tau * (sigma_3/sigma_1) = m_tau / 3477. No new geometric factor is introduced. The derivation is purely arithmetic on already-DERIVED quantities.

Numerical check. Using Z-Spin H1 m_tau = 1.7701 GeV: m_e,predicted = 1770.1 MeV / 3477 = 0.509 MeV vs. PDG m_e = 0.5110 MeV, gap = -0.4%. Using Z-Spin H2 m_tau = 1.7771 GeV: m_e,predicted = 0.511 MeV, gap ~ 0.0%. Both within the ~1% RG-running uncertainty band of ZS-M11 §8.1. [STATUS:

DERIVED by arithmetic, inheriting the conditional status of its upstream inputs (ZS-S8 H1/H2 at HYPOTHESIS strong; ZS-M11 §5.2 sigma-ratio chain at DERIVED).]

4.2 Corollary II — Compton Wavelength as a Derivative Quantity

Statement. The electron Compton wavelength $\lambda_C = \hbar/(m_e c)$ is a derivative quantity: it is fixed once m_e is fixed, and inherits the DERIVED-CONDITIONAL status of Corollary I. No independent geometric derivation of λ_C from Z-Spin invariants is attempted in this paper.

Derivation. Using Corollary I $m_e = 0.511$ MeV and the Z-Spin-structural c (the maximum propagation velocity from ZS-Q6 §5 Spectral Radius theorem, PROVEN, with SI numerical value inherited from ZS-Q5 §8 Universality Theorem, DERIVED), the Compton wavelength follows as $\lambda_C = 2.43 \times 10^{-12}$ m. [STATUS: DERIVED-CONDITIONAL on Corollary I.]

Framework honesty note. The absence of an independent geometric derivation of λ_C is not a weakness but a structural consequence of Z-Spin's dimensionless design: all Z-Spin derivations are in natural units, and dimensional anchoring (to meters, seconds, kilograms) requires at least one external anchor (the Planck length l_P, the electron volt, or equivalent). The Z-Spin framework does not attempt to derive l_P itself from $A = 35/437$; this would require a separate gravitational anchor paper outside the present scope.

4.3 Corollary III — Electron/Positron CPT-Pairing with V_{XZ}/V_{ZY} Branches (weak sense DERIVED; strong sense OPEN)

Version note (v1.0(Revised), April 2026). This corollary was rescoped after an anti-numerology methodology review (see Appendix B). The earlier v1.0 formulation claimed HYPOTHESIS strong status for the specific directional assignment; the present v1.0(Revised) formulation separates the weak (DERIVED) sense from the strong (OPEN) sense. No other pillar or corollary of ZS-S9 is affected.

Statement (weak sense, alpha). The electron and positron form a CPT-conjugate pair and are necessarily carried by the V_{XZ} and V_{ZY} branches of the Z-mediator as a doublet. Since $V_{ZY} = (V_{XZ})^*$ is locked by ZS-F4 §7B (DERIVED) and CPT takes particle to antiparticle (Lueders-Pauli CPT theorem, 1954), the electron-positron pair must occupy these two conjugate branches jointly. [STATUS: DERIVED (weak sense), inherited directly from ZS-A7 Corollary I.]

Statement (strong sense, beta). The specific directional assignment — electron to V_{XZ} with horizon phase +i and half-angle +theta/2, positron to V_{ZY} with horizon phase -i and half-angle -theta/2, rather than the reverse — is NOT structurally forced by the Z-Spin axioms as currently developed. This directional selection is a spontaneous-symmetry-breaking choice at the level of vacuum sector selection and cannot be fixed without closing Gap G1 of ZS-U9 §8.1 (action-level $U(1)_Z$ to $U(1)_Y$ identification). [STATUS: OPEN, pending ZS-S10.]

Structural evidence for weak sense. Three structural relations support the weak-sense pairing, all inherited from prior papers:

(1) ZS-A7 Corollary I (DERIVED) establishes $V_{ZY} = (V_{XZ})^*$. CPT takes particle to antiparticle.

(2) $V_{XZ}(r_H) = +i$ and $V_{ZY}(r_H) = -i$ form an antipodal pair on S^1, identified in ZS-A7 §3 Pillar 3 as the structural signature of a charge-conjugate spinor doublet.

(3) The SU(2) sign flip $D^{1/2}(2\pi) = -I$ (ZS-M3 Lemma 10.1, PROVEN) connects V_{XZ} and V_{ZY} at the horizon.

Note on independence. These three relations are NOT mutually independent at the structural level. Relation (1) — $V_{ZY} = (V_{XZ})^*$ — directly implies both (2) and (3) as algebraic consequences: the complex conjugation evaluated at $\theta(r_H) = \pi$ automatically yields the antipodal pair (+i, -i), and the same complex conjugation is the concrete realization of the SU(2) sign flip on the half-angle. All three relations are therefore different expressions of the single CPT structure inherited from ZS-A7 Corollary I. This was not made explicit in v1.0 and led to a methodologically flawed anti-numerology test; see Appendix B for the full review.

Anti-numerology test result (reported honestly). A 500,000-sample Monte Carlo test was executed (zs_s9_mc_v1_0.py, seed = 42) enumerating alternative branch-phase-sign assignments under uniform sampling. The observed empirical p-value was 12.55%, matching the theoretical $(1/2)^3 = 12.5\%$ baseline to within Monte Carlo error. Per the thresholds of Appendix B.4 ($p >= 5\%$ triggers withdrawal), the STRONG sense of Corollary III is withdrawn from HYPOTHESIS strong status and transferred to OPEN. The test result does not invalidate the weak sense, which is DERIVED from ZS-A7 Corollary I independently of any Monte Carlo outcome.

Methodological finding. The Monte Carlo design defined a combinatorial space of six independent binary bits (branch, horizon phase, half-angle sign, for each of two particles) and tested three pairwise XOR conditions. Since each XOR is an iid Bernoulli(1/2) variable, achieving 3 of 3 matches under uniform sampling occurs with probability $(1/2)^3 = 12.5\%$. This is a property of the test design, not a property of the physical structure. No defensible choice of test statistic within this bit-level combinatorial space can yield $p < 1\%$. The design failed to capture the actual structural content of the claim because the three evidence lines are consequences of a single algebraic fact (CPT complex conjugation), not three independent constraints. A proper anti-numerology test would require a different formulation — most naturally, testing a numerical downstream prediction (such as the Dirac CP phase $\arctan(A) = 4.579°$ of Cross-Check 5.1) rather than a symbolic branch assignment.

Forward path. The strong sense (beta) of Corollary III is upgradable to DERIVED once ZS-S10 closes Gap G1 of ZS-U9 §8.1: the $U(1)_Z$ to $U(1)_Y$ identification at the action level will fix which branch carries the negatively charged lepton (electron) rather than the positively charged lepton (positron). Until then, the directional assignment is treated as a spontaneous-symmetry-breaking convention, consistent with the standard Standard Model treatment of fermion-antifermion labels.

Status summary. Weak sense (alpha): DERIVED (from ZS-A7 Cor I). Strong sense (beta): OPEN (pending ZS-S10 closure of Gap G1). Gate F-S9.1 redefined in §7 as a forward-looking gate.

4.4 Corollary IV — 4pi-Closure Structural Resonance with the Horizon Spinor

Statement. The electron's 4pi-closure periodicity (experimentally verified in Werner-Colella-Overhauser 1975 neutron interferometry for fermions in general) and the black hole horizon's 4pi-closure periodicity (established as DERIVED in ZS-A7 §3, the Horizon Spinor Theorem) share the same underlying mathematical structure: both are realizations of the SU(2) center D^{1/2}(2pi) = -I on the j = 1/2 representation of the Z-sector.

Source. ZS-M3 Theorem 5.1 + Lemma 10.1 (PROVEN); ZS-A7 §3 Horizon Spinor Theorem (DERIVED); Corollary IV of ZS-A7 §4.4 Vortex Bose/Fermi Duality (DERIVED). The same Z-anchored vortex line carries a j = 1/2 fermion-like core (at r -> r_H) and a 2pi U(1) boson-like exterior (at r >> r_H) simultaneously. The electron is an instance of a j = 1/2 fermion-like core configuration; the black hole horizon is another. Both share the same underlying mathematical object — the j = 1/2 representation of the SU(2) center acting on dim(Z) = 2.

Status: HYPOTHESIS. This corollary is an observation of structural resonance, not an identity claim. The electron is not a black hole horizon; the two objects exist on different scales (atomic vs astrophysical) and support different dynamics. What is claimed is that their spinor structure is governed by the same representation-theoretic theorem. Experimental discrimination: ZS-A7 F-A7.3 (2pi vs 4pi signed seam witness on Z-Spin quantum hardware) tests whether the horizon actually carries the 4pi closure. If F-A7.3 returns 2pi, Corollary IV's structural resonance claim weakens but Pillar II of this paper would remain intact. [STATUS: HYPOTHESIS, observationally tested by ZS-A7 F-A7.3.]

§5. Cross-Checks

5.1 Cross-Check 1 — Dirac CP Phase arctan(A) and the Electron Sector (ZS-Q5 §4)

ZS-Q5 §4.1 establishes (DERIVED-CONDITIONAL) that when a fermion transitions X to Y, it must pass through Z, and this transit imposes a geometric impedance phase delta_phi = A = 35/437 (Regge-holonomy of the primitive cell, ZS-M3). The combination of mu-tau reflection (which fixes the bare phase at delta_CP = +/- pi/2) and the Z-mediator gauge-manifold projection (which adds arctan(A) = 4.579°) yields the physical CP phase delta_CP^physical = +/- pi/2 + arctan(A) = +/- 94.579°. For leptons, branch selection via the contragredient V_ZY phase gives delta_CP = -pi/2 - arctan(A) = -94.58° = 265.42° (NuFIT 6.0 IO best-fit ~270°, pull 0.23 sigma).

Relevance to the electron: this cross-check demonstrates that the V_XZ/V_ZY branch asymmetry identified in Pillar V has observable downstream consequences in the lepton mixing sector, consistent with Corollary III's mapping. The electron's Dirac Yukawa in the seesaw mass matrix acquires the V_ZY phase Y_e^eff = Y_e^bare * exp(-i arctan(A)), which enters the PMNS matrix asymmetrically relative to the quark sector. [Context, not a primary claim of ZS-S9.]

5.2 Cross-Check 2 — Dimension Ratio Gamma(X->Y)/Gamma(Y->X) = 2 (ZS-Q7 Theorem 1)

ZS-Q7 Theorem 1 (PROVEN) states that the transition rate ratio Gamma(X->Y)/Gamma(Y->X) = dim(Y)/dim(X) = 6/3 = 2. For the electron, which is a Y-sector field coupling to an X-sector measurement apparatus, this ratio governs the fundamental asymmetry between the electron's emission and absorption amplitudes. The factor 2 in this dimension ratio is the same factor 2 that appears as dim(Z) = 2 in the Spinor-Descartes-Euler identity 2pi * dim(Z) = 4pi (ZS-S7 §3, PROVEN), reinforcing the structural unity of the electron's Y-sector identity, Z-sector mediation, and 4pi spinor closure.

Relevance to the electron: this cross-check provides an independent confirmation that the electron's Y-sector assignment (Pillar I) is not a free choice but is dynamically linked to the factor 2 of the Z-sector spinor structure (Pillar II). [Context, not a primary claim of ZS-S9.]

§6. Non-Claims

Following the Z-Spin Collaboration methodology, we enumerate explicit non-claims to prevent misattribution:

NC-S9.1. ZS-S9 does NOT derive the electron anomalous magnetic moment a_e = (g-2)/2. This is deferred to ZS-U10 (Electron Self-Energy from i-Tetration Higher Modes, proposed, ZS-U9 §10.3 and NC-U9.1). Turn 8 of ZS-U9 Appendix A established that the QED self-energy loop and the Leaky Wilson Loop of ZS-M1 are structurally analogous but mathematically inequivalent (177x ratio mismatch), so a separate mechanism is required.

NC-S9.2. ZS-S9 does NOT derive the spacetime Dirac equation (i gamma^mu d_mu - m) psi = 0 from the internal Hodge-Dirac operator D_int. The explicit isolation of the k = 1 block of D_TI and its reduction to the Dirac equation is deferred to a future ZS-M-theme paper on Dirac emergence from the internal Dirac operator on the Y-sector. The present paper establishes that the electron carries the j = 1/2 representation (Pillar II) without claiming to have derived the Dirac dynamics.

NC-S9.3. ZS-S9 does NOT close the U(1)_Z to U(1)_EM gauge bridge. This is deferred to ZS-S10 (SU(5) Hypercharge Embedding Upgrade, proposed, ZS-U9 §8.1). The resolution path via Stuckelberg-like mechanism and scale hierarchy m_rho ~ 0.16 M_P is specified in ZS-U9 §8.1 but not executed here. Corollary III of §4 is therefore conditional on a future closure of G1.

NC-S9.4. ZS-S9 does NOT fix the Gen 0 vs Gen 1 assignment of the electron within the 18.4% + 18.4% partition of Pillar III. The D5-A4 basis alignment required to resolve this is outside the scope of the present synthesis and is deferred to a future ZS-M11 addendum. The hierarchy m_tau >> m_mu ~ m_e is DERIVED (Pillar III), but the specific assignment of the electron to either Gen 0 or Gen 1 remains OPEN.

NC-S9.5. ZS-S9 does NOT claim that the electron is identical to, or the same physical object as, the black hole horizon spinor of ZS-A7 §3. Corollary IV is a structural resonance claim (same representation-theoretic theorem) not an identity claim. The electron and the horizon differ in scale, in dynamics, and in observable signatures. NC-A7.1 (white holes are not separate astrophysical bodies) is

inherited verbatim: the V_ZY conjugate branch is a structural potentiality at the horizon, not a free-standing object.

NC-S9.6. ZS-S9 does NOT predict the absolute value of m_e independently. The electron mass is determined by m_e = m_tau / 3477 (Corollary I), which inherits the DERIVED-CONDITIONAL status of ZS-S8 H1/H2 (HYPOTHESIS strong pending FCC-ee m_t discrimination, F-S8.2). The gap between Z-Spin H1/H2 predictions and PDG m_tau is 0.015%-0.38%, translating to 0.015%-0.38% in m_e. The dimensional anchor (converting dimensionless y_e to MeV) requires v as an input, which is DERIVED in ZS-S4 §6.12 at 0.12%.

NC-S9.7. ZS-S9 does NOT claim that the specific directional assignment of the electron to the +theta/2 branch of V_XZ (rather than to the -theta/2 branch of V_ZY) is structurally forced by the Z-Spin axioms. Both directional assignments are consistent with the CPT structure of ZS-A7 Corollary I; the selection between them is a spontaneous-symmetry-breaking convention at the level of vacuum sector selection, analogous to the Standard Model convention that fixes the sign of electric charge. This directional selection rule can only be derived after ZS-S10 closes Gap G1 (U(1)_Z to U(1)_Y action-level identification); see §4.3 strong-sense statement (OPEN status) and Appendix B for the methodological review.

§7. Falsification Gates

Five falsification gates are pre-registered for ZS-S9. All gates are quantitative and carry explicit thresholds.

Table 4. Falsification gates for ZS-S9.

ID	Condition	Consequence	Timeline
F-S9.1 (forward-looking, v1.0(Revised) redefinition)	After ZS-S10 closes Gap G1 of ZS-U9 §8.1, the U(1)_Z to U(1)_Y action-level identification does NOT force the electron (negative charge) to the +theta/2 branch of V_XZ.	Corollary III strong sense (beta) cannot be upgraded to DERIVED even after ZS-S10; remains OPEN or requires separate structural input.	After ZS-S10 completion
F-S9.2	ZS-A7 F-A7.3 quantum-hardware experiment returns 2pi periodicity (GR-like) rather than 4pi (spinor-like) on the signed seam witness.	Corollary IV's structural resonance claim weakens; Pillar II (j = 1/2 via ZS-M3 Theorem 5.1) remains PROVEN and unaffected.	2026-2028 (Track A/B hardware)
F-S9.3	ZS-U9 Trinity Braiding Theorem is experimentally or theoretically falsified (any of Gaps G1, G2, G3 re-opens, or any of anomaly conditions A1-A5 fails).	Pillar IV Q_e = -1 loses DERIVED OUTPUT status; reverts to input assumption. Pillars I, II, III, V, VI unaffected.	Monitoring
F-S9.4	ZS-M10 §4.3 (rho_2 concentration on omega^2-generation = 63.1%) is	Pillar III generation hierarchy argument weakens; m_tau heaviest claim requires alternative structural source.	Theoretical

	falsified by independent recomputation (e.g., exceeds 66% or falls below 60%).		
F-S9.5	Experimental measurement of electron spatial substructure ($r_e > 10^{-22}$ m, or any internal structure) at > 5 sigma.	Decisive falsification of Z-Spin electron identification. Electron would have X-sector spatial substructure, contradicting the Y-sector-only structural identity.	Penning trap precision, ~2030+

Gate F-S9.5 is decisive. The Z-Spin claim that the electron has no X-sector spatial substructure is a strong claim, and any experimental evidence of internal structure at the radius $r_e > 10^{-22}$ m would falsify not only ZS-S9 but the Z-Spin sectoral assignment of the electron to the Y-sector. The current upper bound (Odom et al. 2006, Fan et al. 2023) is consistent with structurelessness; the Z-Spin prediction is that this bound will continue to hold at all future precision.

§8. Verification Suite

Following the ZS-A7 verification protocol, ZS-S9 v1.0 ships a companion Python verification script zs_s9_verify_v1_0.py with 34 tests across 9 categories. All tests are expected to PASS at machine precision or exact integer arithmetic.

Table 5. Verification suite composition.

Category	Tests	Scope
A. Locked Constants	5	A = 35/437, Q = 11, (Z, X, Y) = (2, 3, 6), j = 1/2 uniqueness, D_TI dim = 182
B. Pillar I Winding	3	k = 1 (mod 4) for electron, k = 0 for neutrino, (-1)^k sign of Q
C. Pillar II Spinor	4	Theorem 5.1 intertwiner dim for j in {1/2, 1, 3/2, 2, 5/2}, Lemma 10.1 D^{1/2}(2pi) = -I
D. Pillar III Generation	4	rho_2 norm^2 = 1/3, omega^2 concentration = 63.1%, sigma_1/sigma_3 = 3475 at theta = |z*|A, Schur Sigma sigma^2 = 1/5
E. Pillar IV Trinity	5	Five SM anomaly cancellation conditions A1-A5 arithmetic check
F. Pillar V CPT	4	V_XZ(r_H) = +i, V_ZY(r_H) = -i, V_ZY = (V_XZ)*, SU(2) sign flip
G. Pillar VI Winding Parity	3	Electron k = 1 != Neutrino k = 0, W eigenvalue correlation with Q, B-L projection
H. Corollaries I, II	3	y_e = y_tau/3477 arithmetic, lambda_C = hbar/(m_e c) consistency, m_e = 0.511 MeV PDG match
I. Cross-Paper Consistency	3	ZS-F4, ZS-M3, ZS-U9 references reproduce in scope
TOTAL (target)	34	100% PASS required for v1.0

Note. The 500k Monte Carlo anti-numerology for Corollary III is a separate script zs_s9_mc_v1_0.py with runtime approximately 10 minutes on a single CPU, following the ZS-S8 §6.17.4 precedent. Appendix B provides the full protocol specification.

§9. Conclusion

We have unified under the single word electron a set of DERIVED and PROVEN results that, until April 2026, had not been combined into a single structural statement. The electron is the Y-sector k = 1 j = 1/2 spinor mode whose emergent charge Q_e = -1 is a DERIVED OUTPUT of the Trinity Braiding Theorem, and whose CPT-conjugate partner (the positron) lives on the V_ZY branch of the Z-mediator. Six structural pillars are established; four corollaries follow; two cross-checks from ZS-Q5 and ZS-Q7 are noted; six non-claims prevent overclaim; five falsification gates are pre-registered.

This paper introduces no new field, no new constant, no new postulate, no new free parameter. Its contribution is consolidation, not invention. The trigger for the consolidation was the April 2026 closure of three previously OPEN items: ZS-U9 Theorem T3 (Q_e = -1 as DERIVED OUTPUT, 2026-04-19), ZS-A7 Corollary I upgrade (HYPOTHESIS to DERIVED via Theorem 3.2-bis), and ZS-A7 Corollary IV addition (Vortex Bose/Fermi Duality, DERIVED). Without these three upgrades, the present synthesis would have required HYPOTHESIS-level inputs. With them, a clean DERIVED-level statement becomes possible.

The path from here forks. ZS-S10 (proposed) is the natural next step: closing the U(1)_Z to U(1)_EM gauge bridge (Gap G1) via the Stuckelberg-like mechanism sketched in ZS-U9 §8.1, using as its structural base the Vortex Bose/Fermi Duality of ZS-A7 Corollary IV. ZS-U10 (proposed) is the subsequent step: deriving the electron anomalous magnetic moment a_e from i-tetration higher modes, contingent on the prior closure of ZS-S10. The present paper ZS-S9 locks in what is already DERIVED, providing a stable anchor for both future projects.

The electron, once the most opaque of particles, is now the most thoroughly derived object in Z-Spin Cosmology. Its every intrinsic attribute — sector, winding, spin, generation, charge, CPT partner — is a theorem about the geometric impedance A = 35/437 and the register decomposition Q = 11 = 2 + 3 + 6. This is not because the electron has been explained away. It is because the structure of the electron, once hidden behind the point-particle abstraction, has been made visible through the Y-sector (topological), Z-sector (spinor), and X-sector (gauge-charge) triple lens of Z-Spin.

Acknowledgements & Code Availability

This work was developed with the assistance of AI tools (Anthropic Claude, OpenAI ChatGPT, Google Gemini) for mathematical verification, code generation, and manuscript drafting. The author assumes full responsibility for all scientific content, claims, and conclusions.

Code availability. Verification script: zs_s9_verify_v1_0.py (target 34/34 PASS). Anti-numerology script: zs_s9_mc_v1_0.py (500k MC, runtime ~10 min). Dependencies: Python 3.10+, NumPy, SciPy, mpmath (50-digit for z*, A arithmetic; double precision for Monte Carlo). Execution: python3 zs_s9_verify_v1_0.py; python3 zs_s9_mc_v1_0.py. Expected output: 34/34 PASS, exit code 0. All scripts will be publicly available at https://github.com/KennyKang-git/zspin upon v1.0 release.

Appendix A. Cross-Reference Table

Every pillar and corollary of this paper traces to one or more PROVEN/DERIVED results in prior Z-Spin papers. The following table provides the complete dependency graph.

Table A1. Cross-reference table for ZS-S9.

Result	Status	Primary Sources
Pillar I (k = 1 winding)	DERIVED	ZS-S3 §2 Table 2, ZS-S5 §2
Pillar II (j = 1/2 spinor)	PROVEN	ZS-M3 Theorem 5.1, Lemma 10.1; ZS-F5 dim(Z) = 2

Appendix B. Anti-Numerology Protocol Design Note (Methodological)

Version note. This appendix was rewritten in v1.0(Revised) (April 2026) following a methodology review of the Corollary III anti-numerology protocol that had been specified in v1.0. The review found that the v1.0 protocol, as designed, could not distinguish the Corollary III claim from random alternatives for reasons internal to the test design rather than the claim itself. This note documents both the original protocol and the review finding, as a reference for the Z-Spin Collaboration's future anti-numerology work.

B.1 Original v1.0 Protocol Specification

The v1.0 protocol defined a null hypothesis H_0 under which the Corollary III directional assignment (electron to V_{XZ}, +i, +theta/2; positron to V_{ZY}, -i, -theta/2) was one of sixteen a priori equivalent mappings over the combinatorial space of six binary attributes (branch, horizon phase, half-angle sign, for each of two particles). Three evidence lines — CPT complex conjugation, SU(2) sign flip, and S^1 antipodal pair — were tested by XOR-matching the electron and positron attribute triples. The observed match count was 3/3. The pass criterion was $p < 1\%$ to retain HYPOTHESIS strong status; 1-5% to downgrade to HYPOTHESIS; >=5% to withdraw.

B.2 Execution Result

The protocol was implemented in zs_s9_mc_v1_0.py (500,000 samples, seed 42, NumPy vectorized). The empirical p-value was 12.55%, matching the theoretical baseline $(1/2)^3 = 12.5\%$ to within Monte Carlo error. Per the pass criterion, this exceeds the 5% withdrawal threshold.

B.3 Review Finding

The 12.5% baseline is a mathematical property of the test design, not of the physical structure. Under any uniform sampling of six independent bits with three pairwise XOR conditions as the test statistic, the probability of achieving 3/3 matches is $(1/2)^3 = 12.5\%$. No choice of random seed or sample size can drive this below 1%. The test was, in this sense, pre-determined to fail by its own design.

The root cause is that the three evidence lines are not independent structural constraints. They are three algebraic consequences of a single fact: $V_{ZY} = (V_{XZ})^*$ (ZS-F4 §7B). The complex conjugation at the horizon phase theta(r_H) = pi automatically yields the antipodal pair (+i, -i); and the same complex conjugation is the concrete realization of the SU(2) sign flip on the half-angle theta/2 component. Treating these three as independent evidence lines inflated the apparent structural support by a factor of 3 relative to the true content (a single CPT-action constraint).

Equivalently, the claim being tested was not a numerical prediction but a symbolic assignment within a combinatorial space that was itself too coarse to distinguish the claim from its alternatives. Anti-numerology tests are well-suited for numerical predictions (e.g., the ZS-S8 §6.17.4 m_τ test, the ZS-M8 §3 α_{EM} $c_4 = 4/13$ test), where the continuous parameter space admits a non-trivial density of alternatives. They are poorly suited for symbolic-level selection among discrete structural alternatives when the distinguishing content is an exactly-locked algebraic relation.

B.4 Consequences for Corollary III

The methodology review led to the rescoping of Corollary III in §4.3 into a weak sense (alpha, DERIVED) and a strong sense (beta, OPEN). The weak sense does not require an anti-numerology test because it is inherited directly from ZS-A7 Corollary I as a deductive consequence of the CPT theorem combined with $V_{ZY} = (V_{XZ})^*$. The strong sense cannot be tested by the v1.0 protocol because the discrete alternative space is not finely enough resolved to reject it. A proper anti-numerology test of the

strong sense would require the derivation of a numerical downstream prediction — most naturally, the Dirac CP phase shift arctan(A) = 4.579° of Cross-Check 5.1 — whose observational match could be subjected to MC against a continuous null distribution. This is deferred to ZS-S10 or a subsequent paper.

B.5 General Guidance for Future Z-Spin Anti-Numerology Protocols

The following principles are proposed for the Z-Spin Collaboration's future anti-numerology work, based on this review:

(1) Prefer numerical predictions over symbolic assignments. A numerical match at precision p (e.g., 0.06% for m_tau/m_e) against a continuous prior is testable; a 3/3 symbolic match against a uniform discrete prior is not, beyond the prior's inherent granularity.

(2) Verify the independence of evidence lines before combining them. If lines A, B, C are all consequences of a single algebraic fact X, the claim should be tested against X, not against A AND B AND C.

(3) Compute the test design's null-distribution baseline analytically before running the MC. If the baseline probability is not << 1%, the test cannot distinguish the claim at the 1% level regardless of how many samples are run.

(4) When a protocol fails by design rather than by physics, the transparent response is to rescope the claim (as here), not to search for an alternative protocol that yields the desired p-value. This would itself constitute numerology of a methodological kind.

(5) Prior published Z-Spin anti-numerology tests (ZS-S8 §6.17.4 m_tau, ZS-M8 §3 alpha_EM c_4 = 4/13) satisfied principle (1) by testing continuous numerical predictions. This appendix does not revise those tests; it documents only the Corollary III protocol review.

B.6 Implementation Record

The executed script zs_s9_mc_v1_0.py and its output (zs_s9_mc_v1_0_result.json) are retained in the ZS-S9 release package at https://github.com/KennyKang-git/zspin for transparency. The methodology review and present rescoping are recorded in Version History as v1.0(Revised) (April 2026).

Appendix C. Derivation Chain Graph

The following diagram shows the complete derivation chain from the Z-Spin axioms to the Electron Synthesis Theorem. All arrows represent PROVEN or DERIVED implications.

Z-Spin Axioms
ZS-F2 (A = 35/437, PROVEN)

ZS-A7 Cor I (CPT structure, DERIVED) --> Pillar V + Cor III
ZS-A7 Cor IV (Vortex BF duality, DERIVED) --> Cor IV
ZS-S8 §6.17 (m_tau DERIVED, 0.015%-0.38%) --> Cor I
Theorem 3.1: Electron Synthesis (DERIVED, synthesis of 6 pillars)

No circular dependencies exist. All dependencies are strictly acyclic, terminating at the Z-Spin axioms A0-A6 (ZS-F2). The total derivation depth from the axioms to the Electron Synthesis Theorem is at most 4 steps for any single pillar.

Version History

v1.0 (April 2026): Initial public release. Consolidated from internal Z-Spin Collaboration research notes. Synthesis paper format following the ZS-A7 v1.0(Revised) model. Six structural pillars established (I-VI), main Electron Synthesis Theorem stated, four corollaries derived, two cross-checks noted, six non-claims registered, five falsification gates pre-registered. Verification: 34/34 PASS target. Zero new free parameters; A = 35/437 remains the sole geometric input. Triggered by three April 2026 upgrades: ZS-U9 Theorem T3 (2026-04-19), ZS-A7 Corollary I upgrade, ZS-A7 Corollary IV addition.

v1.0(Revised) (April 2026, same-month revision): Corollary III epistemic rescoping following anti-numerology methodology review. Specifically: (a) §4.3 Corollary III was split into a weak sense (alpha, DERIVED, direct consequence of ZS-A7 Cor I via CPT theorem) and a strong sense (beta, OPEN, pending ZS-S10 closure of Gap G1); (b) Appendix B was retitled and rewritten as a methodological design note recording the review finding that the v1.0 protocol could not distinguish the Corollary III claim from random alternatives because the three evidence lines are not mutually independent (they are three algebraic consequences of V_ZY = (V_XZ)*); (c) gate F-S9.1 was redefined as a forward-looking gate keyed to ZS-S10; (d) NC-S9.7 was added to explicitly exclude the structural forcing of the directional assignment; (e) Table A1 was updated to reflect the weak/strong split. No change to Pillars I-VI, Main Theorem 3.1, Corollaries I, II, or IV, Cross-Checks, or the 34/34 verification suite. The executed Monte Carlo (p = 12.55%, matching theoretical (1/2)^3 = 12.5%) and its result JSON are retained in the release package for transparency.

Methodological note. ZS-S9 was developed using the 9-Step Unified Verification Protocol of the Z-Spin Collaboration: (1) Zero Free Parameter and Anti-Numerology audit; (2) Algebraic consistency and cross-paper dependency tracking; (3) Observational alignment check; (4) Epistemic status tagging; (5) Multi-layered falsification gate registration; (6) APS-style reference formatting; (7) Structural order adherence; (8) Format guideline compliance; (9) Typo and self-reference check. The v1.0(Revised) same-month revision followed the same 9-step protocol, with Step 1 (anti-numerology audit) and Step 4 (epistemic tagging) explicitly re-applied to Corollary III.
