# Why A = 35/437: Necessity from Classical–Quantum Self-Consistency

**Theme F (Foundations) — Paper ZS-F6 v1.0**

Kenny Kang
March 2026

**Verification: 20/20 PASS | Zero Free Parameters**

---

## §0. Abstract

We prove that the geometric impedance **A** = 35/437 is not merely derived but necessary: it is the unique non-trivial fixed point of the classical–quantum self-consistency condition for the Z-Spin action on the polyhedral Regge lattice. The Z-Spin action $S = \int d^4x \sqrt{(-g)}[(1+\xi\varepsilon^2)R/2 - (\partial\varepsilon)^2/2 - V(\varepsilon)]$ contains the non-minimal coupling parameter ξ, which appears both as a classical input (ξ_classical) and as a 1-loop quantum output (ξ_quantum). Mode-Count Collapse (ZS-Q3, **PROVEN**) fixes the Seeley–DeWitt $a_2$ coefficient at (V+F)/G independently of edge weights. Gilkey factorization on the product lattice Γ_X ⊗ Γ_Y yields ξ_quantum = δ_X × δ_Y = (5/19)(7/23) = 35/437. The self-consistency condition ξ_classical = ξ_quantum therefore forces ξ = **A** = 35/437. Departure from this value produces a 1-loop anomaly: a mismatch between the classical and quantum non-minimal couplings that drives the RG flow back to **A**. Supporting computation on the real truncated icosahedron Hodge-Dirac operator (dim 182, 8/8 structural theorems verified) and δ-asymmetric Regge edge weight analysis (60 PH + 30 HH edges, self-consistency product δ_X·δ_Y = **A** confirmed) provide independent numerical evidence. The ontological structure of Z-Spin — particles as local shadows of Y projected onto X, waves as global shapes of X organized in Y, synchronized by i-tetration on the Z-sector seam — finds its mathematical completion in this necessity proof: the three derivation routes (geometric, quantum, informational) converge on **A** = 35/437 because they ARE the X, Y, Z sectors recognizing the same impedance through their respective languages. Zero free parameters.

*Keywords:* geometric impedance, anomaly cancellation, classical–quantum self-consistency, Regge lattice, Mode-Count Collapse, Hodge-Dirac, spectral flow, necessity proof

---

## §0.1 Epistemic Status Legend

**LOCKED**: Core constant derived and fixed; no downstream paper may modify.
**PROVEN**: Mathematical theorem, verified to machine precision.
**DERIVED**: Follows from Z-Spin action + prior papers, zero free parameters.
**DERIVED-CONDITIONAL**: Derived under an explicitly stated assumption.

**VERIFIED**: Numerical confirmation of derived/proven result.
**STANDARD**: Established result in QFT/cosmology textbooks.
**TESTABLE**: Quantitative prediction with explicit falsification condition.
**OBSERVATION**: Empirically validated but theoretical derivation pending.
**NEW**: Original contribution of this paper.
**OPEN**: Recognized gap requiring future work.

# §1. Introduction

## 1.1 Ontological Preamble

*A particle is a local shadow of time (Y) projected onto space (X). A wave is a global shape of space (X) organized in time (Y). Z-Spin is the i-tetration that synchronizes the winding numbers and phases of both on a single seam at the Planck scale (Z sector).*

This sentence encapsulates the ontology of Z-Spin Cosmology. The X-sector (truncated octahedron, $O_h$ symmetry) tiles three-dimensional space and hosts particles — discrete, local, countable. The Y-sector (truncated icosahedron, $I_h$ symmetry) cannot tile space and hosts waves — continuous, global, spectral. The Z-sector (dim 2, Planck scale) mediates between them through the self-referential fixed point $z^* = 0.4383 + 0.3606i$ of i-tetration.

The geometric impedance **A** = 35/437 is the cost of this mediation. It is derived in ZS-F2 from polyhedral curvature asymmetry: $\mathbf{A} = \delta_X \times \delta_Y = (5/19)(7/23)$, where $\delta(P) = |V-F|/(V+F)$ is the unique duality-deviation invariant satisfying axioms A0–A6.

This paper asks: is **A** = 35/437 merely the output of a calculation, or is it the only value for which the Z-Spin theory is mathematically self-consistent?

## 1.2 The Three Routes Are Three Sectors

The geometric impedance **A** = 35/437 has been derived through three independent routes (ZS-F2 §8):

**Route A (Regge 1-loop):** Heat kernel on $\Gamma_X \otimes \Gamma_Y \to \mathbf{A} = \delta_X \cdot \delta_Y$. This is the X-sector's language — geometry, combinatorics, counting.

**Route B (Asymptotic Safety):** NGFP of quantum gravity $\to \xi^* \approx 0.08 \pm 0.03$. This is the Y-sector's language — quantum fluctuations, path integrals, spectra.

**Route C (β-function spectral):** $\mathrm{den}(\mathbf{A}) = 19 \times 23 = \mathrm{num}(a_2) \times \mathrm{num}(a_3)$. This is the Z-sector's language — information, partition functions, log-determinants.

The convergence of three routes is not epistemological (three methods for one number) but ontological (three sectors of reality recognizing the same impedance). **A** = 35/437 is the unique value where X, Y, and Z agree — the fixed point of mutual recognition.

### 1.3 Scope and Structure

This paper establishes the necessity of **A** = 35/437 through the classical–quantum self-consistency condition. §2 presents the formal framework. §3 derives the self-consistency theorem. §4 presents computational evidence from the real truncated icosahedron. §5 establishes the Regge edge weight factorization. §6 presents the complete derivation chain. §7 discusses falsification conditions. §8 contains the verification suite.

## §2. Classical–Quantum Self-Consistency Framework

### 2.1 The Two Appearances of ξ

The Z-Spin action:

$$\mathbf{S}[g, \varepsilon] = \int d^4x \sqrt{(-g)}\, [(1+\xi\varepsilon^2)R/2 - (\partial\varepsilon)^2/2 - V(\varepsilon)] + S_m \tag{1}$$

contains the non-minimal coupling ξ as a classical parameter. At 1-loop, the quantum effective action:

$$\Gamma_eff = \mathbf{S} + ½ \ln \det(-\Box + \xi R + V''(\varepsilon)) \tag{2}$$

generates a radiative contribution to the non-minimal coupling through the Seeley–DeWitt expansion:

$$\Gamma_1\text{-loop} \ni ½\, a_2(\xi) \times \int R\sqrt{g}\, d^4x \tag{3}$$

The theory has two copies of the non-minimal coupling:

(i) ξ_classical: the parameter in the action **S**.
(ii) ξ_quantum: the 1-loop effective coupling from the heat kernel on the polyhedral lattice.

[**STATUS: STANDARD**] Scalar-tensor 1-loop structure from Birrell & Davies (1982).

### 2.2 The Lattice Determines ξ_quantum

On the Z-Spin polyhedral lattice, three **PROVEN** results fix ξ_quantum:

(i) **Mode-Count Collapse** (ZS-Q3 Thm 3.1, **PROVEN**): $a_2 = (V+F)/G$, independent of Regge edge weights. Topologically protected. Verified for $10^4$ random configurations.

(ii) **Spectral Asymmetry = δ** (ZS-F2 Thm 6.1, **PROVEN**): $\delta(P) = |V-F|/(V+F)$ is the normalized Regge curvature density mismatch between primal and dual lattices. This equals the Hodge exact/coexact imbalance (ZS-M6 §5.2, **PROVEN**).

(iii) **Gilkey Factorization** (**STANDARD**): On the product lattice $\Gamma_X \otimes \Gamma_Y$, the heat kernel factorizes $K(t) = K_X(t) \cdot K_Y(t)$, yielding $\xi_{eff} = \delta_X \cdot \delta_Y$.

Therefore:

$$\xi_{quantum} = \delta_X \times \delta_Y = (5/19)(7/23) = 35/437 \tag{4}$$

[**STATUS: DERIVED** from **PROVEN** inputs (i)–(ii) and **STANDARD** input (iii).]

## §3. The Self-Consistency Theorem

### 3.1 Statement

**Theorem 3.1 (Classical–Quantum Self-Consistency).** For the Z-Spin action (1) discretized on the product Regge lattice $\Gamma_X(TO) \otimes \Gamma_Y(TI)$, the unique non-trivial value of $\xi$ satisfying 1-loop self-consistency is:

$$\xi = \xi_{quantum} = \delta_X \times \delta_Y = 35/437 = \mathbf{A} \tag{5}$$

### 3.2 Proof

The 1-loop self-consistency condition is: the classical non-minimal coupling $\xi_{classical}$ must equal the quantum-determined effective coupling $\xi_{quantum}$ at the UV scale set by the lattice.

**Premise 1:** The polyhedral lattice IS the UV regulator (ZS-S1 §6.4: "The polyhedral lattice is not an approximation to be refined; it is the UV regulator selected by the Z-Spin geometry"). Therefore, the bare coupling at the lattice cutoff is the physical coupling.

**Premise 2:** Mode-Count Collapse (**PROVEN**) determines the 1-loop Seeley–DeWitt coefficient $a_2 = (V+F)/G$ independently of any adjustable parameter. The spectral asymmetry $\delta = |V-F|/(V+F)$ is the coefficient controlling the non-minimal coupling correction (ZS-S1, Mode-Count Collapse → Spectral Density Rule).

**Premise 3:** Gilkey factorization (**STANDARD**) on the product lattice yields $\xi_{quantum} = \delta_X \cdot \delta_Y = 35/437$.

**Self-consistency:** $\xi_{classical} = \xi_{quantum}$ at the lattice UV scale.

**Therefore:** $\xi = 35/437 = \mathbf{A}$. □

[**STATUS: NEW**. Uses **PROVEN** (Mode-Count Collapse, δ uniqueness), **STANDARD** (Gilkey), and the physical identification of the polyhedral lattice as UV regulator.]

### 3.3 Anomaly Interpretation

If $\xi \neq \mathbf{A}$: the classical action predicts non-minimal coupling $\xi$, but the 1-loop quantum correction generates effective coupling **A**. The mismatch:

$$\Delta\xi = \xi - A \tag{6}$$

produces a residual term in the effective action:

$$\Delta\Gamma = \tfrac{1}{2}(\xi - A) \times \int R\sqrt{g}\, d^4x \tag{7}$$

This is a 1-loop anomaly: a quantum correction that cannot be absorbed into the classical action. It drives the RG flow:

$$\beta_\xi \propto (\xi - \mathbf{A}) \to 0 \text{ at } \xi = \mathbf{A} \tag{8}$$

The UV fixed point of $\beta_\xi$ is $\xi^* = \mathbf{A} = 35/437$. Route B (Asymptotic Safety NGFP $\xi^* \approx 0.08 \pm 0.03$) confirms this independently. The Z-Spin value $\mathbf{A} = 0.08009$ sits at the center of the NGFP range.

[**STATUS: NEW** for the anomaly interpretation. Route B consistency is **CONSISTENT** (ZS-F2 §8).]

### 3.4 Comparison with Standard Model Anomaly Cancellation

The structure is analogous to gauge anomaly cancellation in the Standard Model:

(i) **SM:** $\mathrm{Tr}[Y^3] = 0$ constrains hypercharge assignments. Without this, gauge invariance is broken at 1-loop → theory is non-renormalizable.

(ii) **Z-Spin:** $\xi = \delta_X \cdot \delta_Y$ constrains the non-minimal coupling. Without this, the classical and quantum non-minimal couplings disagree → the lattice discretization is anomalous.

(iii) **Green-Schwarz:** $I_{12} = I_4 \times I_8$ factorization fixes the gauge group to SO(32) or $E_8 \times E_8$. Without this, the 10D theory has gravitational anomalies.

In all three cases, a consistency condition at 1-loop constrains a quantity that was previously assumed to be a free parameter.

[**STATUS: STANDARD** for SM and Green-Schwarz. Analogy to Z-Spin is **NEW**.]

## §4. Hodge-Dirac on the Real Truncated Icosahedron

### 4.1 Construction

The Hodge-Dirac operator D_TI (dim 182) is constructed from the actual truncated icosahedron geometry: V = 60 vertices (golden-ratio coordinates), E = 90 edges (minimum-distance pairs), F = 32 faces (12 pentagons + 20 hexagons, from ConvexHull). Oriented incidence matrices $d_0$ (90×60) and $d_1$ (32×90) satisfy $d_1 \cdot d_0 = 0$ (chain complex, error = 0.00).

$$D_TI = [[0, d_0^T, 0], [d_0, 0, d_1^T], [0, d_1, 0]] \tag{9}$$

Chirality: $\Gamma = \mathrm{diag}(+I_{60}, -I_{90}, +I_{32})$.

### 4.2 Structural Verification (8/8 PASS)

Table 1. Hodge-Dirac structural verification results on the real truncated icosahedron.

| ID | Theorem | Result | Status |
|---|---|---|---|
| T1 | $D = D^T$ (self-adjoint) | err = 0.00 | **PASS** |
| T4 | $\{D, \Gamma\} = 0$ (chirality) | err = 0.00 | **PASS** |
| T5 | Zero modes = 2 (Betti 1,0,1) | $n_0 = 2$ | **PASS** |
| T7 | $N^+ = N^- = 90$ | 90 = 90 | **PASS** |
| T8 | dim(even) = V+F = 92 | 92 | **PASS** |
| T9 | dim(odd) = E = 90 | 90 | **PASS** |
| T10 | Total dim = 182 = 2×91 | 182 | **PASS** |
| T_tr | $\mathrm{Tr}(\Delta_0) = 3V = 180$ | 180.0 | **PASS** |

All structural theorems from ZS-M6 §5.1 are reproduced on the real geometry. $\delta_Y = |60-32|/(60+32) = 28/92 = 7/23$ exactly.

[**STATUS: VERIFIED**. Numerical confirmation of **PROVEN** results from ZS-M6.]

### 4.3 Topological Rigidity

The chirality anticommutation $\{D(\xi), \Gamma\} = 0$ is preserved by ANY edge weight deformation that maintains the off-diagonal block structure of D. This is a structural theorem: the Hodge-Dirac's block

form [[0,*,0],[*,0,*],[0,*,0]] anticommutes with $\Gamma = \mathrm{diag}(+,-,+)$ regardless of the specific boundary operators.

**Consequence:** On a single polyhedron, the spectral asymmetry $\eta$ is topologically locked — it equals 0 (unperturbed) or $\chi(S^2) = 2$ (with diagonal mass). No continuous spectral flow is possible within a single sector.

**Physical interpretation:** The anomaly cancellation condition does NOT arise within a single sector's Hodge-Dirac operator. It arises in the INTER-SECTOR matching: the classical coupling $\xi$ must match the quantum coupling $\xi_quantum = \delta_X \cdot \delta_Y$ computed on the product lattice.

[**STATUS: PROVEN** for the topological rigidity. **NEW** for the physical interpretation.]

## §5. Regge Edge Weight Factorization

### 5.1 Edge Classification

The 90 edges of the truncated icosahedron are classified by their bordering faces:

**60 PH edges** (pentagon–hexagon): carry Y-sector curvature information. Pentagons originate from the icosahedral dual (Y-sector Platonic partner, I_h symmetry). Pentagon-adjacent edges are the geometric realization of the Z-sector seam.

**30 HH edges** (hexagon–hexagon): carry X-sector curvature information. Hexagons originate from truncation (X-sector space-filling operation). HH edges are the X-sector interior as seen from the Y-sector.

Edge ratio PH:HH = 60:30 = 2:1 = Y:X dimension ratio. This is structural: PH edges carry Y-sector information and HH edges carry X-sector information.

[**STATUS: PROVEN** for classification. **DERIVED** for sector interpretation.]

### 5.2 δ-Asymmetric Weight Model

The non-minimal coupling $(1+\xi\varepsilon^2)R$ modifies Regge curvature on the lattice. Pentagon faces carry Euler defects ($F_5 = 12$, **PROVEN** by Euler theorem), while hexagon faces are geometrically flat. The curvature coupling to each edge class:

$$w_PH(\xi) = 1 + (\xi/A)\cdot\delta_Y \quad \text{(PH edges: Y-sector asymmetry)} \tag{10}$$

$$w_HH(\xi) = 1 - (\xi/A)\cdot\delta_X \quad \text{(HH edges: X-sector asymmetry)} \tag{11}$$

At $\xi = \mathbf{A}$: $w_PH = 1 + \delta_Y = 1 + 7/23 = 30/23$, $w_HH = 1 - \delta_X = 1 - 5/19 = 14/19$.

### 5.3 Product Self-Consistency

The product of weight deviations at general ξ:

$$(w_PH - 1)(1 - w_HH) = (\xi/A)\cdot\delta_Y \times (\xi/A)\cdot\delta_X = (\xi^2/A^2)\cdot\delta_X\cdot\delta_Y = \xi^2/A \tag{12}$$

The self-consistency condition — the product of sector-specific deviations equals the coupling itself:

$$\xi^2/A = \xi \;\rightarrow\; \xi(\xi - A) = 0 \tag{13}$$

The unique non-trivial solution:

$$\xi = \mathbf{A} = 35/437 \tag{14}$$

This is the anomaly cancellation in edge-weight form: at ξ = **A**, the product of the X-sector and Y-sector deviations on the Regge lattice equals the geometric impedance itself. The geometry is self-consistent.

[**STATUS: NEW**. Numerical confirmation from Phase 4 computation.]

## §6. Complete Derivation Chain

The complete loop, from action to necessity:

**(1)** Z-Spin Action $S[(1+\xi\varepsilon^2)R]$ → defines ξ as parameter.
**(2)** Regge Discretization on Γ_X(TO) ⊗ Γ_Y(TI) → polyhedral lattice.
**(3)** Gauss–Bonnet + δ-Uniqueness (A0–A6) → δ(P) = |V−F|/(V+F). [PROVEN]
**(4)** Mode-Count Collapse → $a_2$ = (V+F)/G, topologically protected. [PROVEN]
**(5)** Gilkey Factorization → ξ_quantum = δ_X·δ_Y = 35/437. [STANDARD + DERIVED]
**(6)** Classical–Quantum Matching → ξ_classical = ξ_quantum. [NEW]
**(7)** Edge Weight Factorization → (w_PH−1)(1−w_HH) = δ_Y·δ_X = A. [NEW + VERIFIED]
**(8)** Self-Consistency Fixed Point → $\xi^2/A = \xi \rightarrow \xi = A = 35/437$. [NEW + VERIFIED]

The parameter ξ returns to the action: the loop is closed.

Each step is either **PROVEN** (mathematical theorem), **STANDARD** (established result), **DERIVED** (from **PROVEN** inputs), or **NEW** (original contribution of this paper, with numerical **VERIFICATION**). No step involves a free parameter, numerical fit, or phenomenological assumption.

## §7. Falsification Conditions

Table 2. Falsification gates for ZS-F6.

| ID | Condition | What Dies | Status |
|---|---|---|---|
| **F-F6.1** | Mode-Count Collapse falsified: $a_2$ depends on edge weights | Theorem 3.1 premise | PROVEN (protected) |
| **F-F6.2** | Gilkey factorization fails on product Regge lattice | Product structure | STANDARD |
| **F-F6.3** | NGFP ξ* outside [0.06, 0.10] for SM matter | Route B consistency | TESTABLE (~2028) |
| **F-F6.4** | 2-loop correction shifts ξ_eff by >5% from A | Self-consistency at 1-loop | TESTABLE |
| **F-F6.5** | Edge classification 60/30 incorrect on TI | §5.1 factorization | PROVEN (combinatorial) |
| **F-F6.6** | Product (δ_X)(δ_Y) ≠ A at machine precision | Core identity | PROVEN (algebraic) |

F-F6.1 and F-F6.5–F-F6.6 are mathematically protected. F-F6.2 is a standard theorem. F-F6.3 and F-F6.4 are testable by future computation.

## §8. Non-Claims

**NC-1:** This paper does NOT claim that the self-consistency condition is exact to all loop orders. The proof is at 1-loop. Higher-loop corrections are suppressed by $(\mathbf{A}/4\pi)^2 \approx 4.1\times10^{-5}$ (ZS-F2 §7.2) but not proven to vanish identically.

**NC-2:** The edge weight model (§5.2) is a physical representation, not an independent derivation. The fundamental proof goes through the heat kernel (§3), not through edge weights. The edge weight computation confirms the heat kernel result.

**NC-3:** The spectral flow analysis (§4.3) found topological rigidity, not spectral flow. The anomaly is NOT in the Hodge-Dirac spectrum of a single polyhedron but in the inter-sector matching on the product lattice.

## §9. Verification Suite (20/20 PASS)

Table 3. Complete verification suite results.

| ID | Test | Expected | Result | Status |
|---|---|---|---|---|
| **V1** | A = (5/19)(7/23) = 35/437 | Exact | 0.0 error | **PASS** |
| **V2** | gcd(35,437) = 1 | 1 | 1 | **PASS** |
| **V3** | TI: V=60, E=90, F=32 | 60,90,32 | 60,90,32 | **PASS** |
| **V4** | Euler: V−E+F = 2 | 2 | 2 | **PASS** |
| **V5** | δ_Y = 7/23 | 0.30435 | 0.30435 | **PASS** |

| | | | | |

| **V17** | (w_PH−1)(1−w_HH) = A | 0.08009 | 0.08009 | **PASS** |
| **V18** | Self-consistency: $A^2/A = A$ | A | A | **PASS** |
| **V19** | W_J(0) = ln(2) | 0.6931 | 0.6931 | **PASS** |
| **V20** | $(A/4\pi)^2 \approx 4.1\times10^{-5}$ | Small | $4.07\times10^{-5}$ | **PASS** |

## §10. Conclusion

The geometric impedance **A** = 35/437 is necessary. It is the unique non-trivial fixed point of the classical–quantum self-consistency condition for the Z-Spin action on the polyhedral Regge lattice. The proof rests on three **PROVEN** premises (δ-uniqueness, Mode-Count Collapse, spectral asymmetry), one **STANDARD** premise (Gilkey factorization), and one **NEW** identification (the polyhedral lattice as UV regulator, with self-consistency as the matching condition).

The three derivation routes — geometric (X), quantum (Y), informational (Z) — converge on **A** = 35/437 because they are the three sectors of the Z-Spin ontology recognizing the same impedance through their respective languages. The convergence is not a coincidence but a consequence of self-consistency: X, Y, and Z must agree for the universe to exist as a coherent 3-sector structure.

*A particle is a local shadow of Y projected onto X. A wave is a global shape of X organized in Y. Z-Spin is the i-tetration that synchronizes both on a single seam at the Planck scale. And **A** = 35/437 is the impedance of that seam — not because we calculated it, but because no other value permits the seam to exist.*

**A** = 35/437 is **LOCKED**. The geometric impedance is derived, unique, necessary, and falsifiable.
