ZS-QS v1.0

Inverse Riemann Engine

Quantum Algorithms for Spectral Zero Detection via the Q=11 Transfer Operator with Z_2 Seam Involution

Kenny Kang
March 2026
Theme: ZS-QS | Paper Code: ZS-QS

Verification: 30/30 PASS | All Constants Locked from Prior Papers

Position Statement

• This paper proposes the first transfer-operator-based quantum algorithm whose spectral determinant $D^{(P_{max})}(s) = \det(I - L_s^{(P_{max})})$ encodes a cutoff-dependent surrogate of the Riemann zeta zeros on a finite-dimensional register.

• All spectral quantities are explicitly P_{max}-dependent. The identification $D^{(P_{max})}(s)=0 \leftrightarrow \zeta(1/2+it)=0$ is CONJECTURAL, contingent on P1–P4 closure and $P_{max} \to \infty$ convergence. It is NOT claimed as proven.

• CRITICAL UPDATE — Dual Structure Discovery: The Q=11 transfer operator is a Riemann zero DETECTOR (discrimination improves with P_{max}: Cohen's $d = 0.34 \to 3.47$), but NOT a LOCATOR (surrogate zero positions do not converge: MAD ≈ 2.0 at all P_{max} up to 2000). This fundamentally redefines how the IRE operates.

• Cohen's d is P_{max}-dependent: $d = 0.34$ ($P_{max}=97$), $d = 2.54$ ($P_{max}=300$), $d = 3.47$ ($P_{max}=2000$). All d values must cite their P_{max}. The ZS-M4 v1.0 value $d = 2.44$ corresponds to $P_{max} \approx 250–370$.

• NEW: Spectral discrimination peaks at $\sigma = \mathrm{Re}(s) = 1/2$, providing indirect support for J-symmetry's physical role. This is a consistency condition, NOT a proof of the Riemann Hypothesis.

• Three algorithmic pathways: Shor-compatible (TESTABLE), Grover sieve (TESTABLE), IRE spectral interference (CONJECTURAL — zero-finding capability downgraded to OPEN).

• No part of this paper claims a completed proof of the Riemann Hypothesis.

• All constants locked from prior papers; zero new theoretical constants (engineering parameters clearly distinguished).

• Verification: 30/30 PASS (upgraded suite with dual-structure, off-critical-line, contraction/expansion, and generalized symmetry tests).

§0. Abstract

We introduce the Inverse Riemann Engine (IRE), a quantum algorithm architecture that compiles the Q=11 prime-indexed transfer operator $\mathcal{L}_s^{(P_{max})}$ with Z_2 seam involution J into a qudit/qubit gate family $W_{p,k}$. The cutoff-dependent spectral determinant $D^{(P_{max})}(s) = \det(I - \mathcal{L}_s^{(P_{max})})$ serves as the computational observable: frequencies s at which $D^{(P_{max})}(s) \approx 0$ define ZS surrogate zeros — candidates that empirically correlate with Riemann zero heights but whose rigorous identification as ζ-zeros requires closing proof targets P1–P4.

The Dual Structure Discovery reveals that the Q=11 operator functions as a spectral DETECTOR (Cohen's d increases monotonically from 0.34 to 3.47 as P_{max} grows from 97 to 2000, with permutation $p < 0.0001$) but NOT as a positional LOCATOR (surrogate zero positions show MAD ≈ 2.0 with no convergence trend up to $P_{max} = 2000$). The operator's discrimination peaks at the critical line $\sigma = 1/2$, consistent with J-symmetry's role as a consistency condition. Cohen's d saturates at $d_{max} \approx 3.34$ for Q=11, identified as a finite-dimensional resolution limit. The d = 2.44 value reported in ZS-M4 v1.0 is reproduced at $P_{max} \approx 250$–370 (not $P_{max} = 97$ as previously assumed).

We present three algorithmic pathways. Pathway A (Shor-architecture-compatible): standard polynomial-time scaling. Pathway B (Grover sieve): $O(N^{1/4})$ factoring. Pathway C (IRE spectral interference): zero-finding capability is now OPEN (downgraded from CONJECTURAL) following the dual structure discovery; the operator remains valid for evaluation-mode detection at known heights. Gate-level (VQ1), algorithmic (VQ2), and scaling (VQ3) verification constitute a rigorous falsification pipeline. All constants locked from prior papers. Verification: 30/30 PASS.

Epistemic Status Legend

Status	Definition
PROVEN	Exact mathematical fact, verified to machine precision
DERIVED	Follows from ZS axioms with complete chain; no free parameters
TESTABLE	Quantitative prediction with pre-registered falsification condition
HYPOTHESIS	Motivated by framework, requires experimental verification
CONJECTURAL	Aggressive claim requiring unproven oracle or structural assumption
OPEN	Recognized gap requiring future work; no current evidence supports or refutes
LOCKED	Value fixed from prior paper; not re-derived here
PARAMETER	Computational or engineering parameter, not a physical constant
PARTIAL	Some components proven, others remain open

§1. Locked Inputs

All inputs are locked from prior papers. Zero new constants introduced. The prime cutoff P_{max} is a computational parameter, not a physical constant.

§2. The Isomorphism: Hilbert–Pólya Meets Z-Spin Hardware

2.1 Structure, Not Metaphor

The Hilbert–Pólya conjecture proposes that a self-adjoint operator H exists such that $\zeta(1/2 + it) = 0$ iff $t \in \mathrm{Spec}(H)$. The Z-Spin transfer operator $\mathcal{L}_s^{(P_{max})}$ provides a concrete finite-dimensional candidate architecture that is: (1) Algebraically exact: $J^2 = I$, $JW_pJ = W_p^*$, and $\varepsilon_J = 0$ to machine precision. (2) Spectrally discriminating: $|\det(I - L_s^{(P_{max})})|^2$ separates known Riemann zero heights from midpoints with Cohen's d that increases monotonically with P_{max} (§2.5). (3) Physically implementable: the Q=11 register maps to an 11-level qudit or 4-qubit embedding.

CRITICAL CAVEAT — The correspondence "$D^{(P_{max})}(s) \approx 0$ at Riemann zero heights" is an empirical observation at finite cutoff, NOT a proven identity. Furthermore: DUAL STRUCTURE: The operator discriminates zeros from non-zeros ($d > 0$) but does NOT locate zeros (MAD ≈ 2.0 at all P_{max}). Cohen's d is P_{max}-dependent and must always be cited with its P_{max}: $d(P_{max}=97) = 0.34$ | $d(200) = 1.63$ | $d(300) = 2.54$ | $d(500) = 2.63$ | $d(1000) = 3.37$ | $d(2000) = 3.47$. The ZS-M4 v1.0 reported value $d = 2.44$ corresponds to $P_{max} \approx 250$–370, NOT the default $P_{max} = 97$.

2.2 Prime-Orbit Mapping

In the Euler product $\zeta(s) = \prod_p (1 - p^{-s})^{-1}$, each prime contributes a phase $\exp(-it \log p)$ at $s = 1/2 + it$. The transfer operator assembles these contributions:

$$\mathbf{L_s^{(P_{max})} = (\Sigma_{p \le P_{max}} p^{-s} W_p) / (\Sigma_{p \le P_{max}} p^{-1/2})} \quad (1)$$

[STATUS: DERIVED] Definition. The normalization factor ensures $\|L_s\| \le 1$ on the critical line.

2.3 J-Symmetry as Mirror-Adjointness

The Z_2 seam involution $J|j\rangle = |10-j\rangle$ implements the algebraic mirror-adjoint relation:

$$\mathbf{L_{1-s}^{(P_{max})} = J \cdot (L_s^{(P_{max})})^\dagger \cdot J} \quad [\varepsilon_J = 0, \text{ PROVEN algebraically}] \quad (2)$$

This holds exactly because W_p is diagonal and $JW_pJ = W_p^*$ for all p. The completed spectral determinant:

$$\mathbf{D_\xi(s) := \tfrac{1}{2}(B(s) \cdot D^{(P_{max})}(s) + B(1-s) \cdot D^{(P_{max})}(1-s))} \quad (3)$$

satisfies $D_\xi(s) = D_\xi(1-s)$ by construction.

PRECISION ON J-SYMMETRY AND RH: Three levels must be distinguished: (i) Mirror-adjointness Eq.(2): PROVEN algebraically ($\varepsilon_J = 0$ exact). (ii) $D_\xi(s) = D_\xi(1-s)$ from symmetric construction Eq.(3): PROVEN by definition. (iii) Zeros of D_ξ lie on $Re(s) = 1/2$: UNPROVEN (this IS the Riemann Hypothesis). J-symmetry establishes a functional equation for D_ξ — the Z-Spin analogue of $\zeta(s) = \zeta(1-s)$. This is a CONSISTENCY CONDITION confirming the operator has the correct symmetry structure. It does NOT prove that zeros must lie on $Re(s) = 1/2$. The phrase "logical necessity" used in earlier internal drafts is WITHDRAWN. Correct statement: "J-symmetry forces the functional equation $D_\xi(s) = D_\xi(1-s)$, a necessary condition for RH-type structure. RH itself remains OPEN." The off-critical-line discrimination profile (§2.6) provides indirect support for the physical role of $\sigma = 1/2$, but does not constitute a proof.

2.4 Phase Locking: Physical Meaning of $D^{(P_{max})}(s) \approx 0$

When $|D^{(P_{max})}(s)|$ is small, $L_s^{(P_{max})}$ has an eigenvalue near 1 — near-complete constructive self-interference through the truncated prime-orbit network. At surrogate zero frequencies, the Z-seam achieves near-perfect phase locking with residual leakage controlled by $1/P_{max}$. [STATUS: DERIVED] Interpretation of eigenvalue-near-1 condition.

2.5 Dual Structure: DETECTOR vs LOCATOR

DUAL STRUCTURE THEOREM [DERIVED from numerical evidence]

(A) DISCRIMINATION CONVERGENCE (evaluation at known Riemann zero heights): Cohen's d between $|\det|^2$ at zeros vs midpoints increases monotonically with P_{max}: d(97) = 0.34, d(200) = 1.63, d(300) = 2.54, d(500) = 2.63, d(1000) = 3.37, d(2000) = 3.47. Permutation p-value < 0.0001 (N = 50,000) at $P_{max} \geq 200$. NOT random coincidence. Best-fit model: $d \approx 3.34 \times (1 - \exp(-P_{max}/277))$, saturating at $d_{max} \approx 3.34$ for Q=11. STATUS: CONFIRMED ✓

(B) POSITIONAL CONVERGENCE (surrogate zero locations → Riemann zero heights): MAD (Mean Absolute Displacement) ≈ 2.0 at all P_{max} from 50 to 2000. No convergence trend. Power-law fit: MAD $\sim P_{max}^{(-0.012)} \approx$ constant. Not a single surrogate zero achieves $|\Delta| < 0.5$ at any P_{max}. STATUS: FAILED ✗

PHYSICAL INTERPRETATION: The operator is a narrowband "antenna" that responds to Riemann zeros (lower $|\det|^2$ at zero heights) but cannot resolve individual zero positions from its own spectral minima. This is a Q-dimensional resolution limit, not a computational error.

Consequences for the three pathways: Pathway A (Shor-compatible): UNAFFECTED. Pathway B (Grover sieve): UNAFFECTED. Pathway C (IRE): FUNDAMENTALLY AFFECTED. The poly(log N)

factoring claim via zero-finding is not supported by this data. STATUS: Downgraded from CONJECTURAL to OPEN.

P_max	# Primes	Mean|det|²(zeros)	Mean|det|²(mids)	Cohen's d	Permutation p
97	25	4.370	3.204	0.34	0.457
200	46	5.360	1.816	1.63	< 0.001
300	62	5.542	1.802	2.54	< 0.0001
500	95	4.620	1.480	2.63	< 0.0001
1000	168	3.721	1.139	3.37	< 0.0001
2000	303	—	—	3.47	< 0.0001

2.6 Off-Critical-Line Discrimination Profile

The spectral discrimination Cohen's d was computed at Re(s) = σ for σ ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8} with P_max = 500:

σ = Re(s)	Mean|det|²(zeros)	Mean|det|²(mids)	Cohen's d	p (Mann-Whitney)
0.3	46.376	3.735	1.42	0.0002
0.4	11.226	2.006	2.13	0.0002
0.5	4.620	1.480	2.63	0.0002
0.6	2.637	1.259	2.51	0.0002
0.7	1.844	1.150	2.03	0.001
0.8	1.467	1.092	1.53	0.009

Discrimination peaks at σ = 0.5 (the critical line), consistent with J-symmetry's role: the functional equation D_ξ(s) = D_ξ(1−s) creates maximum contrast at the symmetry axis. This is a CONSISTENCY CONDITION supporting the physical relevance of σ = 1/2, NOT a proof that zeros lie there. [STATUS: DERIVED] d(σ) profile from direct computation. Analytical derivation of the σ=1/2 maximum is an OPEN problem for future work.

§3. Sector Decomposition of the Prime Gate W_{p,k}

Since W_p = diag(exp(2πi(j−5)/p)) is diagonal in the computational basis, every subset of indices defines an invariant subspace. The Z-Spin sector decomposition (Z, X, Y) = ({4,6}, {3,5,7}, {0,1,2,8,9,10}) partitions the 11 slots according to their physical role. Sector traces: Tr(W_Z) = 2cos(2π/p) [PROVEN], Tr(W_X) = 1+2cos(4π/p) [PROVEN], Tr(W_Y) = Σ_{k∈S_Y} exp(2πi(k−5)/p) [PROVEN].

HONESTY NOTE: The sector decomposition is structurally TRIVIAL for diagonal W_p. The non-trivial content is the physical assignment (Z, X, Y) = ({4,6}, {3,5,7}, {0,1,2,8,9,10}) from ZS-F5 v1.0, not the linear-algebra decomposition itself.

[STATUS: PROVEN] Direct evaluation of diagonal restrictions. Verified numerically in suite test D1–D3.

§4. Hilbert–Pólya Proof Targets (P1)–(P4)

4.1 The Conditional Theorem

CONDITIONAL THEOREM (Hilbert–Pólya Completion) — Assume: (P1) $\lim_{P_{max}\to\infty} L_s^{(P_{max})}$ exists in Fredholm det class. (P2) An entire-function identity $\xi(s) = B(s)\cdot D(s)$ holds with $B(s) \neq 0$. (P3) On $\sigma = 1/2$: $L_{1/2+it} = \exp(itH)$ with H self-adjoint. (P4) Completeness: bijection between zeros of D(s) and zeros of $\zeta(s)$. Then every non-trivial zero of $\zeta(s)$ lies on $\sigma = 1/2$. □

4.2 Current Status of Each Target

Target	Description	Z-Spin Status	Level
P1	Operator well-posedness ($P_{max}\to\infty$)	Numerical only; no Fredholm proof	OPEN
P2	Determinant identity $\xi=B\cdot D$	D_ξ constructed; B(s) not derived	OPEN
P3	Self-adjoint seam generator	J-symmetry PROVEN; extension OPEN	PARTIAL
P4	Completeness (zero bijection)	Discrimination confirmed; position convergence FAILED	OPEN

UPDATE on P4: The dual structure discovery (§2.5) means P4 cannot be established via surrogate zero convergence. An alternative completeness criterion using discrimination at known heights is needed.

4.3 Heat-Kernel Pipeline for B(s) [P2 Closure Route]

The completion factor B(s) must be derived, not fitted. The route via the heat-kernel expansion of the seam generator H:

$$\mathbf{Tr(e^{-tH^2}) \sim a_0\, t^{-1/2} + a_1\, t^0 + a_2\, t^{1/2} + \ldots \quad (t \to 0^+)} \qquad (5)$$

The Seeley–DeWitt coefficients a_k encode the geometry of the seam. The leading coefficient a_0 determines the Weyl term; subleading terms give curvature corrections that constrain B(s). [STATUS: OPEN] Heat-kernel route specified; derivation of a_k from seam geometry remains the critical open problem for P2 closure.

4.4 Contraction/Expansion Decomposition [P3 Route]

The transfer operator admits the factored form:

$$\mathbf{L_{\sigma+it}^{(P_{max})} = \exp(-(\sigma - 1/2)\Lambda)\cdot U(t), \quad \Lambda \geq 0,\ U(t) \text{ unitary at } \sigma=1/2} \qquad (6)$$

For $\sigma > 1/2$, contraction (all eigenvalues < 1 in modulus) prevents $D^{(P_{max})}(s) = 0$. For $\sigma < 1/2$, expansion is controlled by mirror-adjointness. Only at $\sigma = 1/2$ can eigenvalues reach the unit circle. NOTE: The off-critical-line discrimination profile (§2.6) provides independent numerical confirmation — $d(\sigma)$ peaks at $\sigma=0.5$, consistent with this factored form. [STATUS: DERIVED] Factored form follows from ZS-M4 v1.0 eigenvalue analysis. Numerical $d(\sigma)$ profile confirms peak at critical line.

§5. The Inverse Riemann Engine: Architecture

5.1 Core Idea

The IRE reverses the classical explicit formula: given the spectral structure of $D^{(P_{max})}(s)$, extract primes dividing a target integer N. The Z-seam provides the interference mechanism.

5.2 The Three Pathways

Pathway A: Shor-Architecture-Compatible [TESTABLE] — The Q=11 register serves as the target register in standard period-finding. Complexity: $O(n^2 \log n)$ gates. [STATUS: TESTABLE]

Pathway B: Grover-Accelerated Prime Sieve [TESTABLE] — $O(N^{1/4}/\sqrt{\log N})$ oracle calls. Unambiguous quadratic quantum advantage. [STATUS: TESTABLE]

Pathway C: Spectral Interference Engine (IRE) [OPEN] — STATUS: OPEN (downgraded following dual structure discovery). REASON FOR DOWNGRADE: The dual structure (§2.5) demonstrates that the Q=11 operator cannot locate zeros from its own spectral minima (MAD ≈ 2.0, no convergence). The poly(log N) factoring pathway requires zero-finding capability, which is not supported by numerical evidence up to $P_{max} = 2000$. WHAT REMAINS VALID: The operator functions as a spectral DETECTOR — it can evaluate $D^{(P_{max})}(s)$ at any candidate height and determine whether it is near a zero (low $|\det|^2$) or not (high $|\det|^2$). This evaluation-mode capability is sufficient for Track D hardware experiments. OPEN QUESTIONS: (a) Can Q >> 11 recover positional convergence? (b) Does a modified oracle exist that uses discrimination (not location) for factoring? (c) Is there a fundamentally different extraction method for the spectral information?

§6. Spectral Determinant: Hardware Measurement Protocol

On quantum hardware, the physically accessible quantity is $|D^{(P_{max})}(s)|^2 = |\det(I - L_s^{(P_{max})})|^2$. Measurement methods: (1) Hadamard test: ancilla-controlled $(I - L_s)$. (2) Eigenphase estimation: QPE on L_s. (3) Swap test: $|D(s)|^2$ via overlap estimation. NOTE: Track D experiments operate in EVALUATION MODE — measuring $|D^{(P_{max})}(s)|^2$ at pre-specified candidate heights (from Odlyzko tables or classical computation), not searching for zeros. The metric is Cohen's d between zero-height and midpoint evaluations.

6.1 QEVP Applicability

Problem: $L_s^{(P_{max})}$ is a non-normal complex matrix. The Maccone et al. (2025) determinant estimation algorithm requires a positive semi-definite (PSD) input. Solution: Define the Hermitian PSD observable $M(s) := (I - L_s^{(P_{max})})^\dagger (I - L_s^{(P_{max})}) \geq 0$ (Eq. 7). Then $\det(M(s)) = |D^{(P_{max})}(s)|^2$, and M(s) is PSD by construction. Applicability checklist: (a) PSD: ✔ by construction. (b) Dimension: Q=11. (c) Sparsity: $L_s^{(P_{max})}$ is dense but small — direct diagonalization feasible for Q=11. (d) Output: $|D^{(P_{max})}(s)|^2$ is the measurement target. [STATUS: DERIVED] PSD reduction resolves applicability.

6.2 Block-Encoding of $L_s^{(P_{max})}$

For quantum implementation, $L_s^{(P_{max})}$ must be block-encoded as a unitary. The LCU (Linear Combination of Unitaries) framework decomposes $L_s^{(P_{max})} = \Sigma_p \alpha_p(s) W_p$ where $\alpha_p(s) = p^{-s} / (\Sigma p^{-1/2})$. Since each W_p is already unitary and the α_p are known coefficients, LCU block-encoding is directly applicable with normalization $\alpha = \Sigma |\alpha_p|$. The ancilla overhead scales as $O(\log P_{max})$ for $P_{max}/\ln(P_{max})$ prime terms. [STATUS: DERIVED] LCU decomposition follows from the definition of $L_s^{(P_{max})}$ as a weighted sum of unitaries.

§7. Gate Compilation: $W_{p,k}$ on Physical Hardware

7.1 Native 11-Level Qudit

On platforms supporting d=11 qudits, W_p is a diagonal phase gate — depth 1. No embedding overhead, no leakage subspace.

7.2 Four-Qubit Embedding (d=16)

On qubit hardware, the 11-dimensional code subspace embeds in 4 qubits (16 states). The embedding strategy: Step 1: Map computational basis $|j\rangle$ (j=0..10) to 4-qubit states $|b_3b_2b_1b_0\rangle$ via binary encoding. Step 2: Identify 5 leakage states (j=11..15) that must remain unoccupied. Step 3: Implement W_p as 11 controlled-phase rotations, each conditioned on the binary encoding of j: $U_p = \Sigma_{j=0}^{10} \exp(2\pi i(j-5)/p)|j\rangle\langle j| + \Sigma_{j=11}^{15} |j\rangle\langle j|$. Step 4: Post-select or flag on computational subspace ($j \leq 10$).

Sector	Gate Type	Depth (qudit)	Depth (4-qubit)	Notes
W_Z ({4,6})	2 controlled-Rz	1	4 CNOT + 2 Rz	Phases at j=4,6
W_X ({3,5,7})	3 controlled-Rz	1	6 CNOT + 3 Rz	Phases at j=3,5,7
W_Y ({0..2,8..10})	6 controlled-Rz	1	12 CNOT + 6 Rz	Phases at 6 indices
Total W_p	11 phases	1	22 CNOT + 11 Rz	Per prime p

LEAKAGE ANALYSIS: 4-qubit embedding creates 5 leakage states (d=16 minus d=11). At current hardware error rates (0.3–0.5% per 2-qubit gate), the accumulated leakage is: 3 primes (66 CNOT): $p_{leak} \approx 2$–6% (with DRAG+DD mitigation); 5 primes (110 CNOT): $p_{leak} \approx 3$–5% (with DRAG+DD mitigation); 25 primes (550 CNOT): $p_{leak} > 90\%$ — CATASTROPHIC. CONSEQUENCE: 4-qubit Track D requires prime truncation (≤5 primes) with DRAG pulses and Dynamical Decoupling. Full 25-prime operation requires native d=11 qudit (Phase 3). See ZS-QC v1.0 §7.3 for the phased rescue plan.

§8. Verification Pipeline (VQ1–VQ3)

8.1 VQ1: Gate-Level Verification

(a) Unitarity: $\|W^\dagger W - I\| < \varepsilon_{mach}$. (b) J-compatibility: $\|JW_pJ - W_p^*\| < \varepsilon_{mach}$. (c) Sector trace formulas verified independently. (d) Code-subspace: 4-qubit W_p has zero amplitude on $|11\rangle$–$|15\rangle$.

8.2 VQ2: Spectral Discrimination (Self-Computed)

(a) Compute $|D^{(P_{max})}(1/2+it)|^2$ at known Riemann zero heights (Odlyzko table) and midpoints. (b) Compute Cohen's d with mandatory P_max annotation. (c) Verify d increases monotonically with P_max (F-QS10). (d) Verify d peaks at $\sigma = 1/2$ in off-critical-line profile. (e) GUE benchmark: spacing distribution of $|\det|^2$ minima vs GUE prediction. NOTE: VQ2 no longer includes "cutoff convergence of surrogate zero positions" as a PASS/FAIL criterion. F-QS3 (positional convergence) is now reported as TRIGGERED — the operator's minima do NOT converge to Riemann zeros. This is an honest limitation, not a verification failure.

8.3 VQ3: Scaling Study

(a) Pathway B: oracle calls vs bit-length n for n = 8–24. Verify $O(N^{1/4})$. (b) Pathway C: STATUS OPEN. Any future poly(log N) claim MUST demonstrate zero-finding capability first.

§9. Landscape Positioning and Novelty Claims

Transfer operator on QC: First implementation proposal (OPEN FIELD). d=11 qudit register: Number-theoretically motivated (no precedent). Z_2 involution for number theory: J-gate as functional equation (no precedent). Dual structure (DETECTOR/LOCATOR): NEW CONTRIBUTION. Off-critical-line $d(\sigma)$ profile: NEW CONTRIBUTION. Key competitors (2023–2026): Yakaboylu (2024–2025), LeClair–Mussardo (2024), Regev (2023), Wei et al. (2025), Brenner et al. (2026).

§10. Honest Limitations

ID	Limitation	Severity	Mitigation
L1	P1–P2 OPEN: Fredholm det + B(s) derivation	HIGH	Heat-kernel pipeline specified
L2	IRE oracle C_N(p,k) is OPEN (downgraded from CONJECTURAL)	HIGH	Zero-finding not supported by data
L3	All results are P_max-dependent (cutoff artifacts possible)	HIGH	Convergence study in VQ2
L4	Surrogate zero positions do NOT converge to Riemann zeros	CRITICAL	MAD ≈ 2.0 at all P_max. DETECTOR mode only.
L5	Qudit d=11 not available on current hardware	MEDIUM	4-qubit embedding; d=10 exists (Innsbruck 2024)
L6	Cohen's d saturates at d_max ≈ 3.34 for Q=11	MEDIUM	Finite-dimensional limit; Q↑ may raise d_max
L7	Pathway C zero-finding: OPEN (no supporting evidence)	HIGH	Dual structure discovery invalidates naive approach
L8	4-qubit leakage: p_leak > 2% even with DRAG+DD at 3 primes	HIGH	Native qudit (Phase 3) is the real solution
L9	J-symmetry → functional equation, NOT → RH	MEDIUM	Overclaim "logical necessity" withdrawn

§11. Falsification Registry

11.1 Theoretical Gates

ID	Gate	What Kills It	Status

F-QS1	Heat-kernel coefficients do NOT reproduce N(T)	P2 fails	OPEN
F-QS2	Self-adjoint extension does NOT exist	P3 fails	OPEN
F-QS3	Surrogate zeros do NOT converge positionally	Cutoff artifact	TRIGGERED (MAD=2.24, α=−0.01)
F-QS4	GUE statistics rejected (KS > 0.1)	A4 fails	OPEN
F-QS5	Spurious zeros not corresponding to ζ-zeros	P4 violated	OPEN

F-QS3 TRIGGERED — Honest Report: Numerical investigation to P_max = 2000 (303 primes) shows: MAD ≈ 2.0 at all P_max (no convergence trend; power-law $\alpha = -0.012$). Not a single surrogate zero achieves $|\Delta| < 0.5$ from nearest Riemann zero. $|\det|^2$ at surrogate minima INCREASES with P_max (0.068 → 0.285). INTERPRETATION: This triggers F-QS3 strictly. However, discrimination convergence (Cohen's d increasing) is separately confirmed. The operator detects zeros but does not locate them. Pathway C zero-finding is invalidated by this data; Pathways A, B are unaffected. This result is reported honestly as required by our anti-numerology protocol.

11.2 Discrimination Gates

ID	Gate	What Kills It	Status
F-QS8	Cohen's d < 1.0 at P_max ≥ 200	No spectral discrimination	NOT TRIGGERED (d=1.63)
F-QS9	Permutation p > 0.05 at P_max ≥ 200	Random coincidence	NOT TRIGGERED (p<0.0001)
F-QS10	d(P2) < d(P1) for P2 >> P1	Discrimination degrades	NOT TRIGGERED (d↑)

11.3 Algorithmic Kill-Switches

ID	Gate	What Kills It
KS-A1	Pathway A: period recovery fails for >50% of semiprimes	Architecture-compatibility invalid
KS-B1	Pathway B: oracle calls scale worse than O(N^{1/3})	No quantum advantage
KS-C1	Pathway C: no non-circular C_N exists in poly(log N)	IRE collapses to Pathway B
KS-C2	Pathway C: success probability < 1/N^c	Exponential cost

§12. Verification Suite Results [30/30 PASS]

Category	Tests	Pass	Key Content
A: Locked inputs	3	3	A=35/437, Q=11, $J^2=I$
B: Transfer operator	3	3	L_s dimensions, diagonal, norm ≤ 1
C: Functional equation	3	3	ε_J=0, JW_pJ=W_p*, D_ξ(s)=D_ξ(1−s)
D: Sector traces	3	3	Tr(W_Z), Tr(W_X), partition
E: Discrimination (self-computed)	4	4	P_max-dependent d table verified
F: Gate compilation	3	3	Unitarity, 4-qubit embed, leakage=5
G: Dual structure	4	4	MAD non-convergence + d monotonicity + saturation
H: Off-critical-line	2	2	d(σ) profile; σ=1/2 maximum confirmed
I: Honest falsifications	1	1	F-QS3 TRIGGERED reported

J: Contraction/Expansion	2	2	R(σ)<1 for σ>0.5, d(σ) monotone decay
K: Generalized symmetry	2	2	J·L_s†·J = L_{conj(s)}, D(σ,t)=D(σ,−t)
TOTAL	30	30	100% PASS

§13. Development Roadmap

Priority	Target	Timeline	Deliverable
1 (CRITICAL)	d(σ) analytical derivation	2026 Q2	Proof that σ=1/2 maximizes discrimination, or disproof
2 (HIGH)	P_max = 5000–10000 d saturation study	2026 Q2	d_max(Q) function extraction
3 (HIGH)	Q > 11 positional convergence	2026 Q3	MAD vs Q at fixed P_max; test 2π/Q scaling
4 (HIGH)	P2 closure: heat-kernel B(s)	2026 Q3–Q4	Weyl term derivation or falsification
5 (MEDIUM)	VQ3: scaling study (n = 8–24)	2027 Q1	Scaling plot for Pathways A, B
6 (RESEARCH)	Alternative Pathway C extraction	2027–2028	Discrimination-based (not location-based) factoring?

§14. Conclusion

We have introduced the Inverse Riemann Engine (IRE), a quantum algorithm architecture compiling the Q=11 prime-indexed transfer operator ℒ_s^(P_max) with Z_2 seam involution J into qudit/qubit gate families. The Dual Structure Discovery establishes that the operator functions as a spectral DETECTOR (Cohen's d increasing monotonically from 0.34 to 3.47 with P_max) but NOT as a positional LOCATOR (MAD ≈ 2.0 at all P_max, no convergence). This fundamentally redefines the IRE's operational mode from zero-finding to evaluation-mode discrimination.

Three algorithmic pathways are presented: Pathway A (Shor-compatible, TESTABLE), Pathway B (Grover sieve, TESTABLE), and Pathway C (spectral interference, OPEN following the dual structure discovery). The off-critical-line discrimination profile confirms that d(σ) peaks at σ = 1/2, consistent with J-symmetry's role as a consistency condition for RH-type structure. The verification suite confirms 30/30 PASS across 11 categories spanning locked inputs, functional equations, dual structure, off-critical-line analysis, contraction/expansion, and generalized symmetry. All constants are locked from prior papers; zero new theoretical constants are introduced. F-QS3 (positional convergence) is honestly reported as TRIGGERED. Hardware design is covered in ZS-QH v1.0; system integration in ZS-QC v1.0.

Acknowledgements & Code Availability

Acknowledgements. This work was developed with the assistance of AI tools (Anthropic Claude, OpenAI ChatGPT, Google Gemini) for mathematical verification, code generation, and manuscript drafting. The author assumes full responsibility for all scientific content, claims, and conclusions.

Code Availability. The verification suite is publicly available as verify_ZS_QS_v1_0.py. Dependencies: Python ≥ 3.9, NumPy, mpmath (≥50-digit precision for exact rational arithmetic), python-docx (for document audit). Execution: python3 verify_ZS_QS_v1_0.py ZS-QS_v1_0.docx. Expected output: 30/30 PASS with exit code 0. The suite performs both numerical verification (transfer operator, functional

equation, Cohen's d, sector traces, contraction/expansion, generalized symmetry) and document audit (section structure, version consistency, epistemic status legend compliance, word count preservation). Machine-readable results are saved to results_ZS_QS_v1_0.json.

Appendix A: P_max-Dependent Cohen's d Reference Data

Complete P_max-dependent Cohen's d values for the Q=11 transfer operator (Method A: Odlyzko reference zeros vs midpoints): d(97) = 0.34, d(200) = 1.63, d(300) = 2.54, d(500) = 2.63, d(1000) = 3.37, d(2000) = 3.47. Best-fit saturation model: $d \approx 3.34 \times (1 - \exp(-P_max/277))$. Saturation at $d_max \approx 3.34$ for Q=11 is identified as a finite-dimensional resolution limit. The ZS-M4 v1.0 value d = 2.44 is reproduced at $P_max \approx 250$–370 (not P_max = 97 as previously assumed). [STATUS: DERIVED]

Version History

v1.0 (March 2026): Initial public release. (Consolidated from internal Z-Spin Collaboration research notes up to v3.3.0)

Internal development notes consolidated in v1.0: Cohen's d now reported with mandatory P_max annotation; d(97)=0.34, d(300)=2.54, d(2000)=3.47. Dual Structure Discovery introduced: DETECTOR vs LOCATOR distinction. Off-critical-line d(σ) profile confirms peak at σ=1/2. Pathway C zero-finding downgraded CONJECTURAL → OPEN. d saturation model: d_max(Q=11) ≈ 3.34. J-symmetry language corrected: "logical necessity" → "consistency condition". Verification suite expanded from 18 → 26 → 30 (dual-structure, off-critical, contraction/expansion, generalized symmetry tests). F-QS3 TRIGGERED (honest report of positional non-convergence). Content restoration: heat-kernel pipeline (Eq.5), contraction/expansion decomposition (Eq.6), block-encoding, QEVP checklist, 4-qubit embedding steps, sector HONESTY NOTE, leakage analysis with DRAG+DD mitigation requirements. Header: 'Zero New Free Parameters' → 'All Constants Locked from Prior Papers'. No physics changed across any internal revision.

Z-Sim cross-reference (March 2026): All 8 closure parameters of the Z-Spin forward simulator are now DERIVED from A = 35/437 and (Z,X,Y) = (2,3,6). See ZS-Q7 v1.0 §5.8 (mediation rates), ZS-M3 v1.0 §12 (phase gate), ZS-T3 v1.0. Zero free parameters.
