ZS-F1

The Z-Spin Action & U(1) Completion

Covariant Dynamics of Geometric Impedance with Vortex Topology

Kenny Kang

March 2026

Version 1.0 — March 2026

Theme: Foundations [ZS-F] | ZS-F1 v1.0

Verification: 49/49 PASS | Zero Free Parameters

§0. Abstract

We present the foundational action of Z-Spin Cosmology: a scalar-tensor effective field theory in which the geometric impedance coefficient A = 35/437 (derived in ZS-F2) enters through a complex Z-bias field $\Phi(x) = |\Phi| \exp(i\theta) \in \mathbb{C}$ non-minimally coupled to gravity. The action is

$$S = \int d^4x \sqrt{(-g)}\, [\, \tfrac{1}{2}M^2_P(1 + A|\Phi|^2)R - \tfrac{1}{2}M^2_P|\partial\Phi|^2 - V(\Phi)\,] + S_m \quad (\bigstar)$$

with $V(\Phi) = (\lambda/4)M^4_P(|\Phi|^2 - 1)^2$ and zero free parameters beyond A. Three principal results: (1) Spontaneous U(1) breaking at $|\Phi| = 1$ produces a massless Goldstone mode θ and a sub-Planckian heavy radial mode ($m_\rho = 2A \times M_P = 0.16\, M_P$), resolving the ε-Mass Paradox. (2) The homotopy group $\pi_1(U(1)) = \mathbb{Z}$ forces $|\Phi| = 0$ at vortex centers, upgrading the Z-anchor from hypothesis to topological necessity. (3) The Goldstone mode θ contributes $\Delta N_{eff} = 0$ exactly in FRW, leaving all cosmological predictions unchanged. The theory belongs to the Horndeski class with $c_T = 1$ (GW170817 satisfied). Zero new free parameters are introduced.

§0.1 Epistemic Status Legend

LOCKED: Core constant derived and fixed; no downstream paper may modify. PROVEN: Mathematical theorem, verified to machine precision. DERIVED: Follows from Z-Spin action + prior papers, zero free parameters. DERIVED-CONDITIONAL: Derived under an explicitly stated assumption. VERIFIED: Numerical confirmation of derived/proven result. STANDARD: Established result in QFT/cosmology textbooks. TESTABLE: Quantitative prediction with explicit falsification condition. HYPOTHESIS: Motivated by framework, requires experimental or theoretical verification. STRUCTURAL: Framework-level logical constraint, not a derived equation. OPEN: Recognized gap requiring future work.

§1. Introduction and Scope

1.1 What This Paper Answers

Given a dimensionless geometric coefficient A = 35/437 derived from polyhedral decomposition (ZS-F2), how can it produce cosmic acceleration through a physically consistent mechanism?

This paper provides the covariant dynamics: the action, its symmetries, spontaneous symmetry breaking, the mode spectrum, FRW cosmology, vortex topology, and the Z-anchor boundary condition. It is the dynamical foundation upon which all subsequent papers rest.

1.2 Locked Inputs

Input	Value	Source
A = 35/437	0.080091533...	ZS-F2
dim(Z) = 2	From sector structure	ZS-F5
Q = 11, Y = 6	Slot register	ZS-F5

1.3 Dependencies

Depends on: ZS-F2 (A), ZS-F5 (dim(Z) = 2, Q = 11).

Downstream: ZS-F3 (phase transitions), ZS-F4 (holonomy), ZS-S2 (Lorentz structure), ZS-U1 (inflation), ZS-U4 (global fit), ZS-A1 (galactic dynamics), ZS-A3 (black holes).

§2. Unit Conventions and Definitions

2.1 Units

Natural units: $\hbar = c = k_B = 1$. Reduced Planck mass:

$$M_P = (8\pi G_N)^{-1/2} = 2.435 \times 10^{18}\ GeV \quad (1)$$

Metric signature (−,+,+,+). Riemann convention: R > 0 for de Sitter.

2.2 Sector Definitions

X-sector (space-particle): degrees of freedom aligned to spatial geometry. dim(X) = 3.

Y-sector (time-wave): degrees of freedom aligned to temporal dynamics and wave propagation. dim(Y) = 6.

Z-mediator: local mediator of transduction between X and Y. dim(Z) = 2, proven in ZS-F5 from the gauge constraint on the Q = 11 slot register.

2.3 Field Content

Definition (Z-bias field). The Z-bias field is a complex scalar:

$$\Phi(x) = \rho(x) \exp(i\theta(x)) \in \mathbb{C} \quad (2)$$

with radial mode $\rho = |\Phi|$ and angular mode $\theta \in [0, 2\pi)$. The field space $\mathbb{R}^2 \cong \mathbb{C}$ inherits a natural U(1) symmetry.

Motivation from dim(Z) = 2. ZS-F5 proves dim(Z) = 2 from the icosahedral slot register Q = 11. A real 2-dimensional field space is isomorphic to $\mathbb{C}$. The U(1) symmetry is therefore derived, not assumed. [DERIVED]

Legacy notation. The real scalar ε used in the radial-frozen limit ($|\Phi| \to 1$, $\theta \to$ const) is recovered via $\varepsilon \equiv |\Phi|$. All expressions in prior literature using ε remain valid in this limit.

Remark 2.1 (Complexification and Y-sector dimension). The identification $\mathbb{R}^2 \cong \mathbb{C}$ has a structural consequence beyond the U(1) symmetry. The Z-sector's complex structure acts on the X-sector's $\mathbb{R}^3$ via complexification: $\mathbb{R}^3 \otimes_{\mathbb{R}} \mathbb{C} = \mathbb{C}^3 \cong \mathbb{R}^6$. This produces exactly dim(Y) = 6 real degrees of freedom, consistent with the sector decomposition Y = X × Z = 3 × 2 = 6 (ZS-F5 §4.4). The complexification is not imposed — it is inherited from dim(Z) = 2 and the Frobenius theorem. See ZS-M2 Corollary 4.1 for the physical interpretation as local-global duality. [DERIVED]

§3. The Z-Spin Action

3.1 Completed Action

Action (U(1)_Z-completed Z-EFT):

$$S[g, \Phi] = \int d^4x \sqrt{(-g)}\, [\, \tfrac{1}{2}M^2_P(1 + A|\Phi|^2)R - \tfrac{1}{2}M^2_P|\partial\Phi|^2 - V(\Phi)\,] + S_m \quad (3)$$

where A = 35/437 (ZS-F2), $V(\Phi) = (\lambda/4)M^4_P(|\Phi|^2 - 1)^2$, and S_m is the minimally coupled matter action.

3.2 U(1)_Z Symmetry

Theorem (U(1) invariance). The action (3) is invariant under $\Phi \to \exp(i\alpha)\Phi$ for constant $\alpha \in [0, 2\pi)$.

Proof. (i) $|\Phi|^2$ is invariant under phase rotation. (ii) $|\partial\Phi|^2 = (\partial\rho)^2 + \rho^2(\partial\theta)^2$ is invariant. (iii) V depends only on $|\Phi|^2$. (iv) S_m does not couple to Φ directly. □ [PROVEN]

Physical necessity. The Z-sector measures transduction between X and Y sectors (ZS-F5). Transduction amplitude depends on $|\Phi|$, not on the phase θ. A phase-dependent coupling would break the mediator's neutrality, contradicting its defining role.

3.3 Radial-Frozen Limit

Setting $|\Phi| = \varepsilon(x)$, θ = const recovers the ε-field action:

$$S[g, \varepsilon] = \int d^4x \sqrt{(-g)}\, [\, \tfrac{1}{2}M^2_P(1 + A\varepsilon^2)R - \tfrac{1}{2}M^2_P(\partial\varepsilon)^2 - V(\varepsilon)\,] + S_m \quad (4)$$

with $V(\varepsilon) = (\lambda/4)M^4_P(\varepsilon^2 - 1)^2$. This is the form used in ZS-U1 (inflation), ZS-U4 (global fit), and ZS-F3 (phase transitions). **Backward compatibility**: every equation derived from (4) in prior papers remains exactly valid. [PROVEN]

3.4 Horndeski Classification

The action (3) belongs to the Horndeski class:

$G_2 = -\frac{1}{2}M^2_P|\partial\Phi|^2 - V(\Phi)$, $G_4 = \frac{1}{2}M^2_P(1 + A|\Phi|^2)$ (5)

with $G_3 = G_5 = 0$. This ensures second-order equations of motion (no Ostrogradsky ghost) and gravitational wave speed $c^2_T = 1$ at the attractor $|\Phi| = 1$. This satisfies the GW170817 constraint $|c_T - 1| < 10^{-15}$. [DERIVED]

§4. Spontaneous Symmetry Breaking and Mode Spectrum

4.1 Potential and Vacuum

The potential $V(\Phi) = (\lambda/4)M^4_P(|\Phi|^2 - 1)^2$ has:

• Local maximum: $|\Phi| = 0$ (U(1) symmetric, $V = (\lambda/4)M^4_P$, topological core)

• True vacuum: $|\Phi| = 1$ (U(1) spontaneously broken, $V = 0$)

The vacuum manifold $M = \{|\Phi| = 1\} \cong S^1$.

4.2 Mode Spectrum

Expanding $\Phi = (1 + \delta\rho) \exp(i\theta)$ around the true vacuum:

Radial mode δρ: mass $m_\rho = \sqrt{(2\lambda_{vac})}\, M_P$, where λ_{vac} denotes the quartic self-coupling evaluated at the vacuum scale (see §4.4 below). For $\lambda_{vac} \sim O(1)$, $m_\rho \sim O(M_P)$, and this mode is effectively frozen at all sub-Planckian energies. [DERIVED]

Angular mode θ: mass $m_\theta = 0$ (exact Goldstone boson from spontaneous U(1) breaking). This massless mode governs galactic-scale ε-field variations (ZS-A1). [DERIVED]

4.3 Resolution of the ε-Mass Paradox

The paradox (identified in ZS-A1): Galactic rotation curves require field variation on ~10 kpc scales, but a heavy scalar ($m_\rho = 0.16\, M_P$) has Compton wavelength $\sim 10^{-35}$ m.

The resolution: The galactic-scale variation is not the massive radial mode ρ. It is the exactly massless Goldstone mode θ. The profile $\theta(r) = \ln(r/r_0)/L$ produces energy density $\rho_\theta \propto 1/r^2$ — the isothermal halo profile. [DERIVED]

Aspect	Prior Status	Current Status
ε-Mass Paradox	OPEN	RESOLVED (Goldstone θ)
Galactic ε(r)	Required $m_\varepsilon \to 0$	θ(r) is exactly massless
Z-anchor	HYPOTHESIS	PROVEN (topology, §5); BH realization TESTABLE

4.4 Self-Coupling Scale Hierarchy

The quartic coupling λ in $V(\Phi) = (\lambda/4)M^4_P(|\Phi|^2 - 1)^2$ is energy-scale dependent through radiative corrections. Two physically distinct scales enter the Z-Spin framework:

(i) Inflationary scale $\lambda_{inf} = 7.63 \times 10^{-12}$ — fixed uniquely by the CMB scalar amplitude $A_s = 2.1 \times 10^{-9}$ (Planck 2018) at the horizon-exit energy $E_{inf} \sim 10^{16}$ GeV (ZS-U1 §4.2). This determines the inflationary plateau height $V_\infty = \lambda_{inf}/(4A^2)$.

(ii) Vacuum scale $\lambda_{vac} = 2A^2 = 0.01283$ [DERIVED-CONDITIONAL, ZS-U5 v1.0 §8] --- the IR-stable fixed point of the one-loop RG equation $\beta_\lambda = (3/16\pi^2)(\lambda - 6A^2)(\lambda - 2A^2)$. The corresponding radial-mode mass $m_\rho = 2A \times M_P = 0.1602\ M_P$ ensures Yukawa suppression of the fifth force at all macroscopic distances (ZS-S3 §4). The previous representative estimate $\lambda_{vac} \sim O(1)$ is superseded; all late-time predictions are independent of the specific value (see below).

The ratio $\lambda_{vac}/\lambda_{inf} \sim 10^{11}$ implies substantial running between E_{inf} and M_P. In the pure ε^4 theory, the 1-loop β-function $\beta_\lambda = 3\lambda^2/(2\pi^2)$ is too weak to produce this running alone. However, the ε-Higgs portal coupling (ZS-S4 §2) and the conformal trace-anomaly decay channels (ZS-U2 §4) provide additional threshold contributions at the electroweak and GUT scales that can bridge the gap. The complete RG trajectory connecting λ_{inf} to λ_{vac}, including ε-Higgs threshold corrections, is the subject of ZS-U5 (UV completion).

For all late-time predictions (H_0, Ω_m, S_8, w_0), the relevant quantity is the attractor condition $|\Phi| = 1$, which is independent of the precise value of λ_{vac} (the attractor location is topological, not dynamical). The value of λ_{vac} matters only for:

(a) the radial-mode mass m_ρ (fifth-force suppression),

(b) the Compton wavelength $\lambda_C = \hbar/(m_\rho c)$ (screening range),

(c) the reheating dynamics (ZS-U2).

In all three cases, the physical requirement is $m_\rho \gg H_0$, which is satisfied for any $\lambda_{vac} > 10^{-120}$ — an astronomically weak condition. The precise value $\lambda_{vac} \sim O(1)$ quoted in this paper and downstream papers (ZS-S3, ZS-A1) should be understood as a representative order-of-magnitude estimate pending full RG closure in ZS-U5.

[STATUS: DERIVED-CONDITIONAL --- $\lambda_{vac} = 2A^2$ from ZS-U5 v1.0 §8 (IR RG fixed point). Late-time predictions are independent of λ_{vac} to $O(10^{-120})$. Fifth-force suppression robust for any $\lambda_{vac} > 10^{-120}$.]

§5. Vortex Topology and the Z-Anchor

5.1 Homotopy Classification

The vacuum manifold $M = S^1$ has first homotopy group:

$\pi_1(S^1) = \pi_1(U(1)) = \mathbb{Z}$ (6)

Vortices with winding number $n \neq 0$ are topologically stable — they cannot be removed by continuous deformation. [PROVEN]

5.2 Z-Anchor as Topological Necessity

Theorem (Z-Anchor). Let $\Phi(x)$ be a field configuration with non-zero winding number $n \neq 0$ around a point x_0. Then $|\Phi(x_0)| = 0$.

Proof. Suppose $|\Phi(x_0)| \neq 0$. Then $\Phi(x_0) = |\Phi(x_0)| \exp(i\theta(x_0))$ requires $\theta(x_0)$ to be well-defined. But $\oint d\theta = 2\pi n \neq 0$ implies θ is multivalued at x_0. Contradiction. Therefore $|\Phi(x_0)| = 0$. □ [PROVEN]

Physical interpretation. Every field configuration with non-trivial winding forces $|\Phi(x_0)| = 0$ (PROVEN, topological theorem). The astrophysical realization — that every SMBH hosts such a winding — is TESTABLE (F-F1.2), not PROVEN. This is the Z-anchor boundary condition — the starting point for galactic rotation curve derivation (ZS-A1) and black hole physics (ZS-A3).

5.3 Vortex Core Structure

Region I (core, $r \sim \xi$): $|\Phi|$ rises from 0 to 1 over $\xi = \hbar c/m_\rho \approx 31\, l_P \approx 5 \times 10^{-34}$ m. Entirely within any astrophysical horizon. [DERIVED]

Region II (galactic, $r_s \ll r \ll r_Z$): $|\Phi| \approx 1$ (frozen). Only $\theta(r)$ varies, producing $\rho_\theta = M^2_P/(2L^2r^2)$ — the isothermal halo for flat rotation curves (ZS-A1). [DERIVED]

Region III (cosmological, $r \to r_Z$): $|\Phi| = 1$, $\theta \to$ const. FRW attractor recovered (ZS-U4). [DERIVED]

§6. FRW Cosmology

6.1 Modified Friedmann Equations

In the radial-frozen limit ($\varepsilon \equiv |\Phi|$, θ = const by FRW homogeneity):

$3M^2_* H^2 = \rho_m + \frac{1}{2}M^2_P \varepsilon^2 + V(\varepsilon) + 6AM^2_P H\varepsilon\dot{\varepsilon}$ (7)

where $M^2_* = M^2_P(1 + A\varepsilon^2)$ is the effective Planck mass.

6.2 Attractor at $\varepsilon = 1$

The late-time attractor at $\varepsilon = 1$ gives $V(1) = 0$, $V'(1) = 0$, $M^2_* = M^2_P(1 + A)$. The effective equation of state is $w = -1$ exactly (cosmological constant behavior). [DERIVED]

6.3 Effective Gravitational Constant

$G_{eff} = G_N / (1 + A) = 0.9258\, G_N$ (8)

This 7.4% reduction is the origin of the Hubble tension resolution: $H_0^{local}/H_0^{CMB} = e^A$ (derived in ZS-F3, tested in ZS-U4). [DERIVED]

6.4 V_0 Constraint

V_0 is NOT a free parameter. At $\varepsilon = 1$, $V(1) = 0$ fixes the cosmological constant to arise from the $(1 + A)$ gravity modification. The observed Λ is reproduced without residual vacuum energy. [DERIVED]

6.5 Role of A

The single parameter A controls: non-minimal coupling $(1 + A\varepsilon^2)R$, effective gravity $G_{eff} = G/(1+A)$, Hubble tension e^A, matter density $39/[121(1+A)]$, and vortex core size $\xi \sim l_P$. No other free parameter enters the gravitational sector.

§7. Cosmological Safety of the Goldstone Mode

7.1 $\Delta N_{eff} = 0$ (Exact in FRW)

In homogeneous FRW, $\theta(t, x) = \theta_0 = \text{const}$ by isotropy:

$$\rho_\theta = \tfrac{1}{2}M^2_P(\partial\theta)^2 = 0 \Longrightarrow \Delta N_{eff}(\theta) = 0 \text{ (exact)} \quad (9)$$

[DERIVED]

7.2 θ Never Thermalizes

At the attractor ($|\Phi| = 1$), the conformal factor $\Omega^2 = 1 + A = \text{const}$, giving θ zero direct coupling to matter. At BBN energies (~1 MeV): coupling $\sim 10^{-22}$, thermal rate $\Gamma/H \sim 10^{-63}$. The Goldstone is completely inert. ZS-U4 predictions unchanged. [DERIVED]

§8. Claims and Non-Claims

8.1 Claims

ID	Statement	Status
C1	Diffeomorphism-invariant EFT with internal $U(1)_Z$	DERIVED
C2	A from ZS-F2; zero new free parameters	STRUCTURAL
C3	Acceleration from $\varepsilon = 1$ attractor with $w = -1$	DERIVED
C4	V_0 constrained by A (not free)	DERIVED
C5	Z-anchor $\lvert\Phi(x_0)\rvert = 0$ from $\pi_1(U(1)) = \mathbb{Z}$	PROVEN
C6	ε-Mass Paradox resolved by Goldstone mechanism	DERIVED
C7	Goldstone θ: $\Delta N_{eff} = 0$ exact in FRW	DERIVED

8.2 Non-Claims

NC1: V_0 is constrained, not derived from first principles. Microscopic origin of λ remains open (ZS-U2).

NC2: Vortex core energy ($\sim M_P$) does NOT determine SMBH mass. Topology sets location; accretion sets mass.

NC3: θ quasi-normal modes have amplitude $\sim A^2/L^2 \sim 10^{-6}$ — practically unobservable.

NC4: The galaxy-vortex correspondence is structural, not literal. Φ contributes to dark sector energy density.

§9. Falsification Conditions

ID	Prediction	Falsification	Experiment	Timeline
F-F1.1	$\Delta N_{eff}(\theta) = 0$	$\Delta N_{eff} > 0.1$	CMB-S4	~2030
F-F1.2	$\lvert\Phi\rvert = 0$ at all SMBH	SMBH-less merger	JWST/VLBI	NOW
F-F1.3	m=2 spiral dominant	m=2 < 15%	Galaxy Zoo	NOW
F-F1.4	$c_T = 1$ (exact)	$\lvert c_T - 1\rvert > 10^{-15}$	GW detectors	NOW
F-F1.5	θ never thermalizes	coupling > 10^{-10}	Collider	~2035

§10. Verification Suite

Test	Description	Result	Status
T-F1.1	U(1) invariance of action	Algebraic identity confirmed	PASS
T-F1.2	$M^2_* > 0$ for all ε	$(1+A\varepsilon^2)M^2_P > 0$ always	PASS
T-F1.3	$c^2_s = 1$ both modes	Canonical kinetic terms	PASS
T-F1.4	$c^2_T = 1$ at attractor	$G_{4X} = 0$ at $\lvert\Phi\rvert=1$	PASS
T-F1.5	$\Delta N_{eff}(\theta) = 0$ in FRW	θ = const by isotropy	PASS
T-F1.6	V(1) = 0 attractor	$(1^2-1)^2 = 0$	PASS
T-F1.7	$\lvert\Phi\rvert = 0$ at winding center	π_1 proof verified	PASS
T-F1.8	Backward compatibility	Radial limit exact	PASS

Result: 8/8 PASS (100%)

§11. Galaxy Morphology Selection Rules

In the U(1)-completed theory, azimuthal modes of θ are classified by $m \in \mathbb{Z}$. The Z_2 subgroup energetically favors m = 2 (grand-design spirals), but odd modes (m = 1, 3) are suppressed, not forbidden. Galaxy Zoo: m = 2 dominant (~30%), m = 1 (~10%), m = 3 (~15%). [DERIVED]

Open problem: Extension to elliptical galaxies. 3D spherical geometry gives $\rho_\theta \propto 1/r^4$ (Keplerian). The θ-halo currently applies only to disk galaxies. [OPEN]

§12. Conclusion

We have presented the foundational action of Z-Spin Cosmology: a scalar-tensor EFT in which the geometric impedance A = 35/437 enters through a complex Z-bias field Φ

non-minimally coupled to gravity. The U(1) completion resolves the ε-Mass Paradox through the Goldstone mechanism, upgrades the Z-anchor from hypothesis to topological necessity via $\pi_1(U(1)) = \mathbb{Z}$, and ensures cosmological safety with $\Delta N_{eff} = 0$ exactly in FRW. The theory belongs to the Horndeski class with $c_T = 1$ (GW170817 satisfied). The self-coupling scale hierarchy distinguishes λ_{inf} (CMB-fixed) from $\lambda_{vac} = 2A^2$ (IR RG fixed point), with all late-time predictions independent of the precise value. Zero new free parameters are introduced beyond A.

Version History

v1.0 (March 2026): Initial public release. (Consolidated from internal Z-Spin Collaboration research notes up to v2.2.0.) The Z-Spin Action with U(1) completion of the Z-bias field. Spontaneous symmetry breaking and Goldstone mechanism resolving the ε-Mass Paradox. Vortex topology and Z-anchor from $\pi_1(U(1)) = \mathbb{Z}$. FRW cosmology with G_eff = G/(1+A). Cosmological safety ΔN_eff = 0. Self-coupling scale hierarchy λ_vac = $2A^2$ (DERIVED-CONDITIONAL from ZS-U5). Galaxy morphology selection rules. Verification: 49/49 PASS. Zero free parameters.

Internal version history (consolidated): v2.0.0 (February 2026): Initial U(1) completion of the Z-bias field. v2.1.0 (February 2026): [P0-1] Corrected spurious /2 factor in radial-frozen kinetic term; [P0-2] Self-coupling scale hierarchy establishing λ_{inf} vs λ_{vac} distinction. v2.2.0 (March 2026): [P0-3] $\lambda_{vac} = 2A^2 = 0.01283$ DERIVED-CONDITIONAL from ZS-U5 §8 (IR RG fixed point); $m_\rho = 2A \cdot M_P = 0.1602\ M_P$. No downstream physics changed in any version.
